Handsome new offices in the Drexel building have been taken, and the new company have already several large contracts, one for an electric railway in the South, and one for a complete central station alternating current lighting plant, including engines, boilers, buildings, etc., to be erected near Philadelphia.

The capital of the new company is $50,000, and the officers are as follows: J. A. McKee, of the Tradesmen's National Bank, president; H. J. M. Cardeza, of Cardeza, Gilliams & Co., secretary and treasurer; W. A. Stadelman, manager and chief engineer. Directors: J. A. McKee, J. L. Stadelman, L. Gilliams, F. D. LaLanne, W. A. Stadelman.

NEW ENGLAND TRADE NOTES.

THE STANDARD ELECTRIC CO., OF VERMONT, have sold a 100-light plant to the Contrexeville Manufacturing Company, of Manville, R. I.

THE TROPICAL AMERICAN TELEPHONE CO., of Boston, besides the regular American Bell Telephone set, of which they have recently received a large consignment from the American Bell Telephone Company, are now offering for export, a new Tropical American Telephone Company export set, the magnets having platinum points, and all latest improvements. They are also making the "Williams" switch-board in a new form, after the style of the multiple switch-board, and have it in all sizes, and are exchanging these for old style boards or old style magneto bells on very reasonable terms. The new export set, offered at $15, is guaranteed to be first-class in every particular, and long distance telephone sets are now sold at the price formerly asked for the American Bell set.

THE STANDARD ELECTRIC SUPPLY CO. have secured the agency for the New England States of the New England switch, manufactured by O. S. Platt, of Bridgeport, Conn. These switches are mounted on wooden or porcelain bases as required, and vary in size from 10 to 100 amperes. They are already having a wide sale.

W. S. HILL, of Boston, has just brought out another of his well-known type of switches, this time for arc or series circuits. The switch is described in another column of this number and is well worthy of careful inspection.

WESTERN TRADE NOTES.

THE BELDING MOTOR AND MANUFACTURING CO., with offices in The Rookery, Chicago, are busy equipping a large factory for the manufacture of their well known motors. They have purchased 10 acres of land on the West Side 5¼ miles from the court house on the Milwaukee and St. Paul road, and the factory formerly occupied by the Garfield Locomotive Works. They are fitting it up with the latest and most approved machinery and expect to do away with belting and long lines of shafting altogether, transmitting their power and running the different departments with electric motors. They have some valuable contracts on hand, one for fifty 20 h. p. motors. Mr. C. H. Bunker, former secretary of the Abbott Buggy Company, of this city, has been elected secretary and treasurer of the company. Mr. N. S. Possons, who has been the general superintendent of the Brush Electric Company for 12 years past, has been appointed to fill the same position with this company for a term of years. Mr. Harold P. Brown has been appointed electrical engineer. The company expect to be in their new factory and able to turn out a number of street car motors a day besides taking care of their rapidly increasing motor business by the first of January.

MR. GEORGE CUTTER has resigned from the managership of The Great Western Electric Supply Co., and, it is rumored, has associated himself with Mr. Kempt, manager of the Brush Company, of this city.

THE CENTRAL ELECTRIC CO. have just booked orders for one hundred miles of improved Candee line wire to be used in alternating current work. This wire has achieved a most enviable reputation on account of its many excellent qualities for pole work and combines high insulation, toughness and remarkable durability. Their trade in other lines is proportionately as good and the amount of business they handle is continually increasing, due to the excellence of their goods and equitable business methods.

ST. LOUIS TRADE NOTES.

GUIDO PANTALEONI, Western representative of the Westinghouse Electric Co., has closed contracts for an installation of 1,500 lights for the Lincoln, Neb., Gas Company, the old Lincoln Electric Light Co. having been sold to the gas company. The entire station will be rebuilt. The total capacity of the station will be 4,000 lights. The meter system will be used.

The Westinghouse station in South Omaha will install 1,000 lights, making their total capacity 1,750 lights. The meter system will be introduced. Kirksville, Mo., has contracted for the installation of 750 lights, Rich Hill, Mo., 500 lights, Mason City, Ills., 750, Mt. Vernon Car Co., Mt. Vernon, Ills., 300 lights, Rockport, Tex., 750 lights, Taylor, Tex., 750 lights. Contracts have also been closed for an electric railway equipment of 12 cars at Salt Lake City, Utah, and 10 cars at Terre Haute, Ind. The Westinghouse electric railways at Springfield, Mo., and Pittsburg, Kan., and Des Moines, Iowa, have been finished and are now in successful operation.

W. L. ARNOLD, who has been looking after the interests of the Excelsior constant current motor for a year past, has disposed of 17 motors. Among late sales was a 2 h. p. Excelsior motor to the Mound City Roll Paper Co., 2 h. p. motor to Julius Buechel, printer, and 1 h. p. motor to Hy. Sallwasser.

THE
Electrical Engineer.

VOL. X. NOVEMBER 26, 1890. No. 134.

LIGHTING THE COUNTRY SEAT OF VICE-PRESIDENT MORTON.

BY M. C. SULLIVAN.

EVERY feature of the electrical industry becomes interesting to the electrical engineer and the public in just that proportion that it proves its value by the most severe and convincing of all tests—Time, and it is generally admitted that those electrical inventions and devices which testify to their usefulness by actual service in the home, the public building, the street and on the railroad, must be considered as applications of the electric current that become necessities.

On a recent visit to Ellerslie-on-the-Hudson, it has been the pleasure of the writer to witness the continued successful operation of the electric lighting plant installed in the country residence of Vice-President Levi P. Morton, after nearly three years actual service. This installation has many interesting features, and can be considered as a model of its kind, it being one of the places where the great utility of the storage battery in the lighting of a country home is clearly demonstrated.

In lighting such a home as this, situated a long distance from any city, by electricity direct, the dynamo cannot be kept constantly running, notwithstanding the importance of having the light always ready for use, whether one or the whole number of lamps installed are needed, and it is here that the storage battery plays an important part in electric illumination.

This plant, Figs. 1 and 2, was installed in the spring of 1888. It consists of 198 15 L accumulator cells manufactured by the Accumulator Co., of this city. These cells are coupled in 6 groups of 33 each. These groups are connected in series by a transfer switch on each rack when being charged from the dynamo situated nearly half a mile away, but are coupled in multiple when supplying current to the lamps. With a current of 40 amperes, requiring 28 mechanical horse-power, the cells can be charged in 8 hours; or, with a current of 30 amperes, requiring 21 horse-power, in 10 hours. They are operated on the following basis:

When the batteries are fully charged they have a capacity equivalent to 1800 ampere hours, which can be discharged in any quantity up to 250 amperes, which is the maximum point of discharge. Sixty volt Sawyer-Man lamps are used, requiring .84 ampere each, so that 300 lamps can be lighted at once, and the battery will sustain the entire number continuously for 7 hours. The regulation of the lamps is accomplished by cutting in or out an extra cell in each series by means of a switch placed on the switchboard on each rack shown in the cut.

The E. M. F. of a storage battery falls slightly as it becomes discharged, and this drop is provided for by the introduction of an additional cell or two in the series.

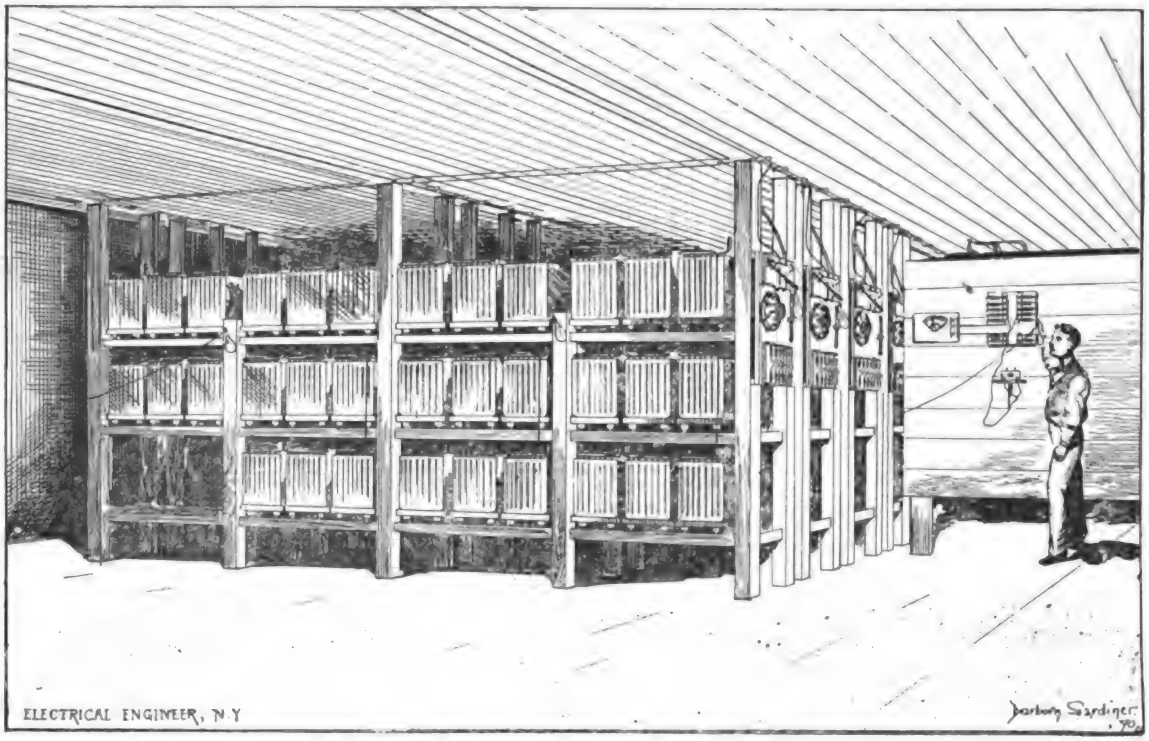

FIG. 1.—ACCUMULATOR PLANT IN RESIDENCE OF LEVI P. MORTON, RHINECLIFF, N. Y.

The above is what the plant is capable of doing, and the time taken to charge it is based on the inquiry: How much current has been taken from them? The E. M. F. of the battery is never allowed to drop below 2 volts per cell. The time required to charge these batteries depends, of course, on the amount of current used since the preceding charge. The method which has been adopted is to commence charging with the amperemeter reading 33, and as the cells become charged the pointer moves back to 25 or 28, or thereabouts.

The average number of lamps burned each day is 85 for about 5 hours, the greatest number of lamps in use at any one time being 250. This average holds good for every day in the week, and it is only necessary to run the engine for 15 hours during that period to charge the batteries, so that 7 hours operation one day and 8 hours another is sufficient to generate the requisite current for the week. This is done in the day time. In this way the dynamo becomes simply an inexhaustible source of supply, while the batteries do the active work.

The dynamo used is a specially shunt wound Thomson-Houston, having a capacity of 30 amperes and 500 volts at 1250 revolutions per minute.

The apparatus connecting the dynamo with the batteries is so arranged that should an accident happen whereby the E. M. F. of the dynamo falls below that of the cells when being charged, no trouble will ensue, as an automatic switch will immediately open the circuit.

When the batteries are fully charged, the wires which are used to conduct the current from the dynamo to the cells are utilized to conduct back sufficient current to light the engine house, dairy and cattle barns. These buildings are located half a mile from the mansion. They are fitted with all modern appliances and conveniences, and the sight of cows and sheep eating by the aid of the incandescent lamp makes one believe that primitive nature is already, as it should be, on the friendliest terms with the most advanced department of science.

The wires from the engine house (a pretty piece of architecture shown in the initial letter of this article) to the battery-room, which is located in the cellar of the mansion, are run underground. For half the distance the Standard underground cable is used; the other half, Grimshaw "White Core," placed in Georgia pine troughing to prevent mechanical injury to the insulation.

The stable and laundry, situated some distance from the house, is lighted from the batteries, the wires being run underground.

The feature of a constant supply of current brings to notice a novel and interesting department of burglar alarm signals. The wiring of the house is so arranged that should any window or door be tampered with, a special automatic switching device will throw into circuit a number of lights, thus giving the nocturnal visitor a bright and warm welcome.

The engine used to drive the dynamo is a 35 h. p. Straight Line engine, which, with steam equipment, was installed by Messrs. Potter and Williams, of New York.

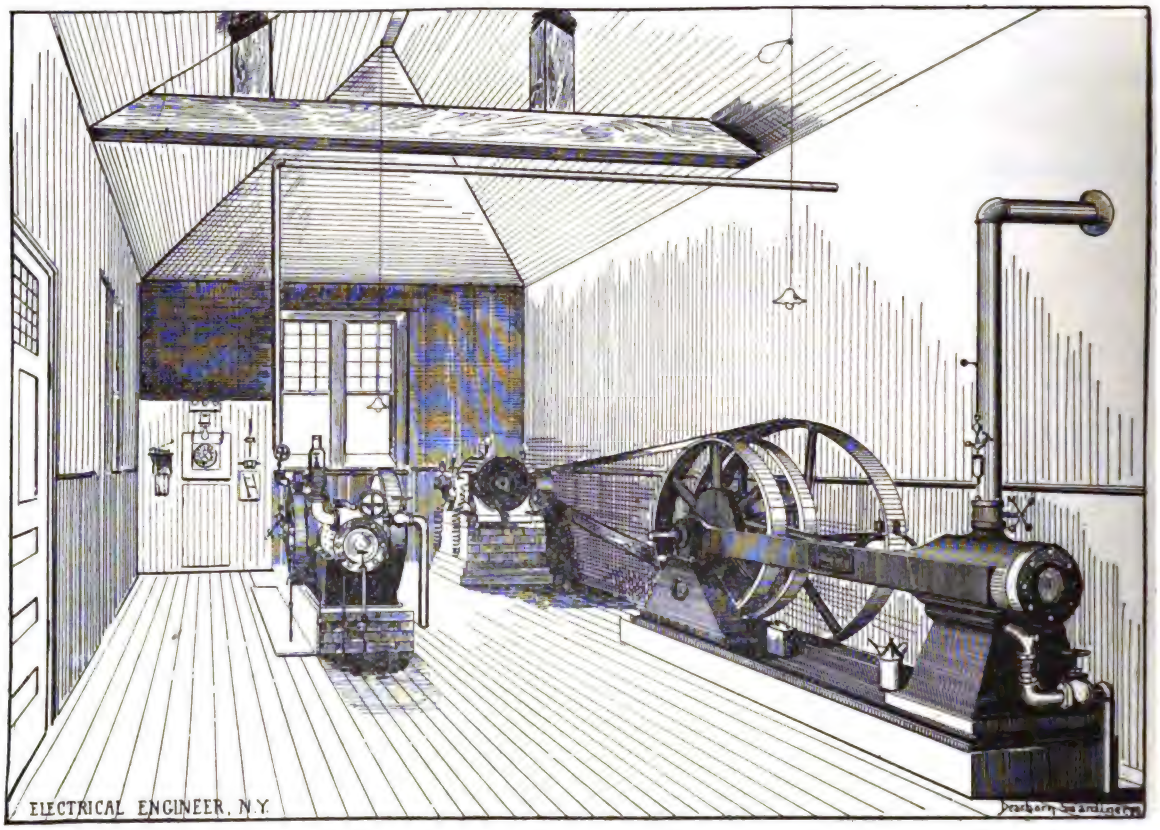

FIG. 2.—DYNAMO ROOM, ELECTRIC LIGHTING PLANT, RHINECLIFF, N. Y.

A journey through these grounds at night is a treat. One finds the electric lamp everywhere, but no other evidence of an incandescent system. There is no engine house in operation with its whirr of machinery and pillar of smoke so common in isolated plants. The lamps draw their life blood from some hidden mysterious source, and the visitor comes away impressed with the perfection and beauty of the incandescent lamp as a means of illumination.

An isolated gasoline plant was installed to provide against any drawback in the electric system. While this is a wise precaution that no fault need be found with, three years experience has not once called it into use to do service while its powerful rival "nodded."

A recent examination of the plant does not disclose any trace of deterioration, and the cells and apparatus are, to the personal knowledge of the writer, who assisted in making the installation in 1887, in as good condition as when turned over to the engineer since in charge of them.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—II.

BY HERBERT LAWS WEBB.

HAVING seen just what is done in each test, let us now proceed to examine the actual instruments required for carrying them out and the methods of connecting up the instruments in practice.

GALVANOMETERS.

The most important instrument in any testing outfit is the galvanometer, as it is by means of the indications of the galvanometer that comparisons are made between the wires or cables to be tested and the standard instruments, such as high resistances, condensers and resistance coils.

The galvanometer usually employed for fine testing is that known as the Thomson reflecting galvanometer; this instrument is made in a great number of different forms,

Fig. 8.—Astatic Galvanometer.

of which it will be necessary for our purposes to describe only the two or three which are most used in general work.

The usual form of the astatic reflecting galvanometer is shown in Fig. 8. It consists of a hard rubber base mounted on three leveling screws and provided with either a circular level or two short spirit-levels placed at right angles to each other, so that the instrument may be accurately leveled when set up. Mounted perpendicularly on the base are the four galvanometer coils, the two at the rear being fixed and the front two hinged so that the astatic needle system can be removed if necessary. At the top of the brass frame to which the coils are attached is a hole into which fits a small brass stud. From the lower part of this stud is suspended, by a single fibre of raw silk, the astatic system of needles, consisting of two small pieces of steel, strongly magnetized, connected together by a fine aluminum wire, the N pole of the lower needle being beneath the S pole of the upper. By this arrangement the directive force of the earth's magnetism is minimized and greater sensitiveness obtained.

To the upper needle is attached a small mirror by means of which a spot of light is reflected on to a graduated scale; at right angles to the lower needle a small vane is fixed in order to check the swinging of the needles and bring them to rest quickly. The brass stud from which the needles are suspended can be lowered so that the vane rests on the coils; all strain is then taken off the silk fibre and the instrument can be moved without risk of breaking the fibre, but it should never be carried about without taking this precaution.

In raising the brass stud care should be taken to merely press it gently upwards by squeezing the fingers in between the head of the stud and the frame; on no account *twist* the stud, as in this way torsion would be put into the fibre and trouble from unequal deflections on opposite sides of the scale would be the result.

The coils are enclosed by a case of brass with plate glass front and back, or by a glass cylinder.

To the top of the case is fixed a rod which supports a very weak permanent magnet by which the needles may be directed so as to bring the spot to any part of the scale; by lowering or raising the magnet on the rod the sensitiveness of the needle may be diminished or increased. For fine adjustments the rod and magnet can be turned together by a tangent screw on the top of the case.

For reading the deflections of this galvanometer a lamp and scale are provided, the light from the lamp being focussed on the mirror of the galvanometer, which reflects back a spot of light on the scale. The scale is usually of cardboard and is divided into 360 divisions on each side of the zero. The spot of light may be either a fine narrow streak covering about one division of the scale, or a round spot with a black line across the centre, the line being produced by a fine wire being stretched across the orifice behind the lens. For a cardboard scale the round spot with the black line is preferable, as the part of the scale on each side of the deflection is illuminated and readings can be made with greater comfort to the observer. Many prefer using a ground glass scale, which is ruled in the same manner as the cardboard scale. The lamp in this case is placed at the side of the scale and the beam of light is reflected to the galvanometer by means of a small mirror mounted on an arm having a universal joint. The observer stands behind the scale, instead of in front of it, and the "spot" appears to him as a line of light on the dark ground glass. With this kind of scale a capital spot can be obtained by using as the source of light an incandescent lamp with a very straight filament, and either getting the two legs of the filament in line, or, better still, so arranging the lamp that one leg of the filament only is reflected by the mirror. In this way a sharply defined line of light is obtained and very close readings can be made.

The advantages of the ground glass scale are that the spot can be seen plainly even though the testing room is very light, and, that as the observer has not to place himself at one side of the scale but directly behind it, he is in a better position for manipulating the instruments and can allow himself more sea-room in setting them up. About the only disadvantage is that it is necessary to follow the movements of the spot pretty closely as it is almost invisible except from exactly behind the part of the scale to which it is deflected.

In setting up the galvanometer care should be taken to select a steady place. In cable factories a masonry pedestal with a good foundation, and not touched by any other part of the building, is generally constructed for the purpose, and in this way the galvanometer is kept free from vibration or jarring. In many places, however, such facilities are not obtainable and it is often necessary to set up the instruments in a room on an upper story, and in a building where heavy machinery is working almost continually. It then becomes necessary to resort to various

devices to free the galvanometer from the effects of the vibration of the building. If the building is of very solid construction a substantial shelf, firmly fixed to the wall, should provide a steady place; if vibration is still felt, a sheet of rubber or some thick rubber rings should be placed on the shelf and above this a heavy slab of lead, the galvanometer being placed on top.

The most sightly way of arranging this is to have a neat wooden case for containing the lead, which may be run in melted or in the form of fine shot. If this plan does not answer, a tray of sand may be substituted for the rubber, the weight being placed on the sand. The last expedient of all is to suspend the galvanometer by means of springs.

The usual plan is to place the galvanometer on a tray hung from a bracket by four coiled brass springs about three feet long. The tray is damped either by means of vanes working in air-tight boxes below, or by fixing brushes at the sides, the brushes just bearing against the edges of the tray. By this arrangement all vibration may be got rid of, but great care is needed in moving about not to touch the springs, or, in fact, any part of the hanging tray as the least jar is sufficient to set the needle dancing for some minutes.

When the galvanometer is set up it should be placed on a dry surface and the hard rubber base should be clean and dry; if there is any likelihood of moisture being present in the air, small pieces or cups of hard rubber should be put under the leveling screws in order that the instrument may be thoroughly insulated. When possible it is best to place the galvanometer facing west, the needles being north and south; but it is often necessary to have it face east, according to the position of the room set apart for testing.

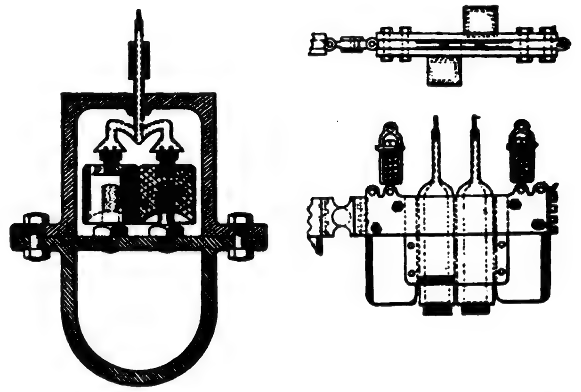
A good astatic galvanometer will not be affected by magnetic disturbances if the disturbing influences are more than a very short distance away, but if magnets, or iron tools, etc., are being constantly moved about within ten or twenty feet of the galvanometer, some sort of magnetic shield will be required to avoid the oscillations of the needle which would be the natural result. The most effective magnetic shield is an old iron safe, a hole being cut in the door large enough to allow of the free transmission of the beam from the mirror when the needle is deflected to its fullest extent. A box of sheet iron will be found more manageable than a safe and may be suspended from springs in the manner described above, thus getting rid both of vibration and magnetic disturbance.

The principal objection to the use of an iron shield completely enclosing the galvanometer is the inconvenience in altering the height or position of the directing magnet. The best combination of magnetic shield and hanging tray is to have the iron box supported on a shelf, and the galvanometer suspended by means of springs passing through holes in the top of the box. To obviate the difficulty referred to above, of altering the position of the directing magnet without disturbing the galvanometer, the rod supporting the magnet is fixed to the under part of the top of the iron box, and the tangent screw is prolonged so that the milled head is outside the box. In this manner the magnet can be raised or lowered without touching the galvanometer, and the direction of the magnet can be altered by means of the screw without opening the box. Such an arrangement as this is a very efficient preventitive both for magnetic and mechanical disturbances, and it has the advantage that the parts of the suspended spring contrivance which would ordinarily be exposed to accidental jarring are rendered inaccessible by being enclosed in the iron box.

The regular pattern astatic reflecting galvanometer is generally wound to about 8,000 or 10,000 ohms resistance, and sometimes even higher. The fine silk-covered wire is wound on four separate bobbins, as already described; the ends of the coils are led to eight terminals on the base plate, four in front and four in the rear, and by varying the connections between these terminals, the combined resistance of the four coils may be varied. A diagram of these connections is always supplied by the manufacturer, but for general work it is rarely, if ever, necessary to use the coils in any other manner than all in series, so as to obtain the maximum resistance.

CAPT. TROTT'S CONDUIT BRUSH CONTACT.

Past experience has shown that in addition to the insulation of the conductors in the conduit great care must be taken to prevent leakage of the current through the wires attached to the contact plow and leading to the motor. To guard against this, Capt. Samuel Trott, of the cable ship "Minia," has designed a brush contact, which, besides insulating the conductors leading to the motor, protects them from abrasion. As will be seen in the accompanying engravings, Figs. 1, 2 and 3, which show the



Figs. 1, 2 and 3.—Trott's Conduit Brush Holder.

brush in different views, respectively, each of the conductors is encased in insulating material, and at the point where the brush is attached to its holder the insulating material is spread out into the form of a hood, in order to protect the brush from falling moisture, the brush being arranged vertically to make contact with the upper surface of the conducting-rail. The two insulated conductors are enclosed in a carrier which travels in the slot of the conduit, and are thus protected from injury by contact with the conduit or any obstruction or foreign matter which may collect in the slot. The carrier is made of two thin plates which clamp the insulated conductors between them, the plates receiving between them at each end and being screwed to a thick vertical plate which acts as a plow. The carrier is supported from the car by means of a spring at each end. This device constitutes an elastic connection between the car and the carrier and enables the brushes to be readily adjusted in relation to the conducting-rails. Those sides of the hood which cross the conducting-rail have lipped edges, by which means the falling moisture is deposited upon each side of the conducting-rail.

CHEMICALLY PURE ZINC.

According to *l'Electricien*, M. Cahaigne, of Paris, has succeeded in producing chemically pure zinc on a commercial scale and at a price but little higher than that of ordinary zinc. MM. Pouchard, Mathieux et Cie., makers of electric clocks, have used Cahaigne zinc rods in the Leclanché cells employed by them. The cells in question furnished current for about 90 hours, and the consumption of the chemically pure zinc amounted to 28 grms. per cell, while the consumption of ordinary well-amalgamated zincs amounted to 36 to 38 grms. The Cahaigne zinc was, moreover, uniformly consumed, while the amalgamated rods were very irregularly attacked.

THE CITY AND SOUTH LONDON RAILWAY.[1]

This railway, which was opened on Nov. 4, is a subway, passing from a point in King William street, City, under the Thames, and on to Stockwell, which has been constructed on a novel method, designed by Mr. Greathead, M. I. C. E., in the form of two circular iron tunnels, 10

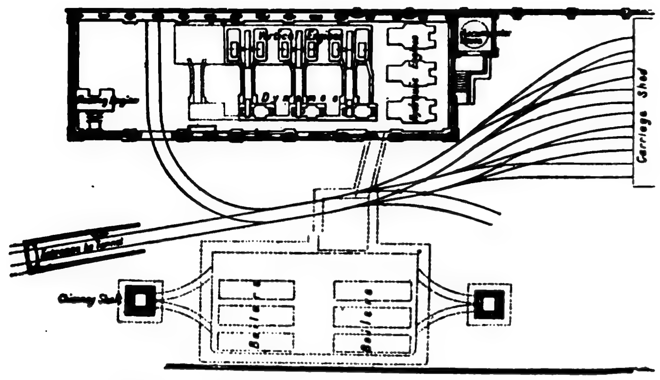


Fig. 1.—Plan of Generating Station.

feet in diameter, driven throughout the London clay, and about 60 feet below the surface.

The two tunnels, which reach from King William's Statue, in the city, to Stockwell, after having passed under the bed of the Thames, have been executed by the compressed air system in the face of a subterranean difficulty which could hardly be exceeded—namely, a powerful underground river, percolating through a gravel bed of large flints and coarse pebbles. This water-flow was kept back for weeks upon weeks by the sheer force of volumes of compressed air, whilst concrete and cement-grout were poured in front of the tunnel shield, and an artificial rock extemporized, in which the segments of the iron tunnel tube could be bolted together.

All the anxieties of the engineering work are over, the rails of the road are laid, the platforms erected, and the neatly constructed underground stations, with their walls lined with white glazed tiles, are ready for the passengers, and have a cleaner and brighter aspect than any of the other underground stations in London. Moreover, they will not be sullied with smoke and dirt from steam locomotives.

A scheme to work this railway by electricity to avoid

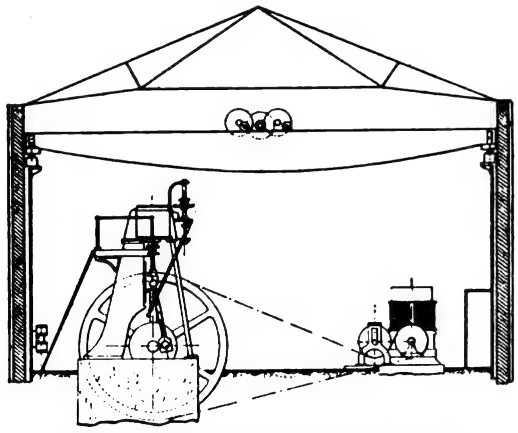

Fig. 2.—Engine and Dynamo Room.

the use of steam and its noxious results, or the use of rope traction with slow speed and other disadvantages, was submitted to the company by Messrs. Mather and Platt, engineers, Manchester. The company accepted the scheme, which is entirely original in its main features, though based upon the experience obtained by Dr. Edward Hopkinson, a partner of the above firm, in the construction of the Bessbrook and Newry narrow-gauge electrical railway in Ireland. The contract for the carrying out of the whole scheme, designed by Messrs. Mather and Platt, was committed to that firm. They have employed Messrs. John Fowler & Co., of Leeds, to supply the boilers and engines to work the dynamos for generating the current of electricity; also, Messrs. Beyer, Peacock & Co. to construct the framework of their electrical locomotives. The whole electrical plant has been carried out under the special superintendence of Dr. Edward Hopkinson, F. R. S., who has acted throughout as consulting engineer, with Mr. G. A. Grindle as resident engineer.

The following are the particulars of the plan of Messrs. Mather and Platt, and details of various parts of the work:

The whole of the plant for generating the electrical current is situated at Stockwell, the suburban terminus of the line. At this point a complete plant, Fig. 1, has been erected for the generation of the current. There are three large generator dynamos of the Edison-Hopkinson type, each worked independently by a vertical compound engine, designed and constructed by Messrs. John Fowler & Co., Fig. 2.

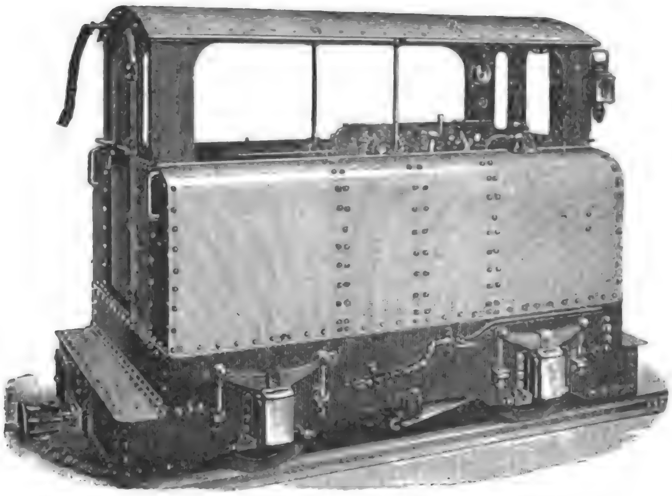

Fig. 3.—Electric Locomotive, City and South London Railway.

The engines work at a steam pressure of 140 lbs. per square inch, and have been built of exceptionally massive proportions. They run at 100 revolutions per minute, giving a piston speed of 450 feet per minute. They are fitted with automatic expansion gear of improved type on both the high and low pressure cylinders, and are controlled by a powerful governor, having a capacity of 750 foot-pounds, which is driven direct from the crank-shaft by cotton ropes. The automatic gear is so arranged as to cut off the steam, if necessary, in both cylinders from dead cut-off to three-quarters of stroke. The engines will indicate up to 375 h. p. each. The cylinders are steam-jacketted, the high-pressure is 17 inches diameter, and the low-pressure 27 inches.

The engines are supplied with steam from six Lancashire boilers, 7 feet diameter by 28 feet long, which are fitted with Vicar's mechanical stokers. Two large feed water heaters are also supplied, with brass tubes of ample surface, for receiving the whole of the exhaust steam from the engine without back pressure.

The generator dynamos are of the Edison-Hopkinson type, with bar armatures, fitted with all the latest improvements of Messrs. Mather and Platt. The weight of the armature alone is about 2 tons, and the weight of the entire machine something over 17 tons. Each machine is capable of generating 450 volts and 450 amperes. The commutators are of hard copper insulated with mica, and

1. London *Electrical Review*.

there are three brushes on each rocking arm, each separately adjustable, with bring-forward thrust and hold-off catch. The magnet limbs are exceedingly massive, each limb, with its pole piece, weighing over 4 tons, and the yoke of the machine weighs about 3 tons.

The machine can be run as compound, or shunt, only, as required. The total weight of copper wire on the magnet of each machine is nearly 1½ tons. The Edison-Hopkinson dynamo is well known as being perhaps the most efficient machine constructed. The present machines have an electrical efficiency of 96 per cent., or slightly over, and the measured efficiency of the engine and dynamo, *i. e.*, ratio of the electric power available outside the dynamo to the indicated h. p. of the engine, is over 75 per cent.

Sir William Thomson's multicellular electrostatic voltmeters are used for measuring the electromotive force. The current from the dynamos is conveyed to a general distributing and testing switchboard, fixed in a recess of the engine house. From this board the main circuits are taken to various parts of the line, and the current passing through each circuit is measured, and suitable arrangements are provided for switching over from one circuit to another.

The site occupied is a plot of about two or three acres on the surface, or ground level. The access between the depot

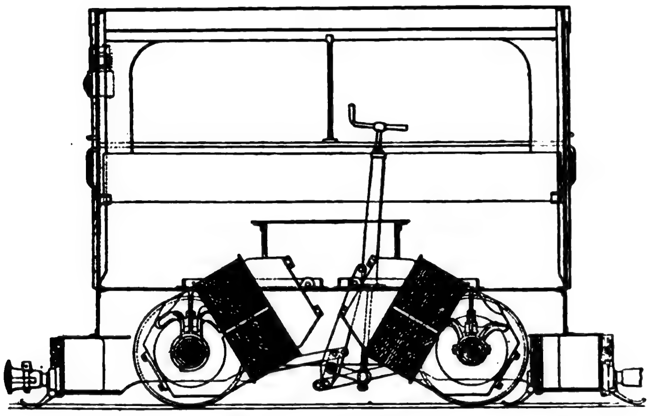

FIG. 4.—ELECTRIC LOCOMOTIVE WITH DIRECT DRIVERS.

and the subway is by a curved tunnel descending from above ground by a steep incline of 1 in 3½ feet. Up and down this the trains are brought or lowered by a rope and winding engine. This short bit of tunnel is remarkable. Formed on a horizontal radius of 250 feet and a severe vertical radius, it is marvelous that the junction of the two drivings, one from below and the other from above, should have met centre for centre and level for level within an inch or two. At the depot the carriage shed is large enough to contain six trains side by side.

The main cables have been manufactured by the Fowler-Waring Co., of North Woolwich, and consist of a copper core of 61/14 B. W. G., insulated with Fowler-Waring insulating material, and lead-sheathed.

The working conductor is of channel steel, carried on glass insulators, the joints being fished and also connected with copper strips. The general arrangement of the working conductor is exactly the same as that employed by Dr. Edward Hopkinson on the Bessbrook and Newry line. The steel employed is of very high conductivity, and has been rolled specially for the purpose by the Shelton Iron and Steel Co., of Stoke-on-Trent. The working conductor is divided into sections for convenience of testing and carrying out repairs on the permanent way. The insulation obtained is extraordinarily high. When the full pressure of 500 volts is on the complete system of working and feeding conductors, the leakage current does not exceed one ampere, so that the total loss by leakage is less than 1 h. p.; this is a small fraction of 1 per cent. of the total power required for working the line to its full capacity. The current is collected from the working conductor by sliding shoes of iron or steel arranged in a very similar way to that employed on the Bessbrook line.

Fourteen 10-ton electric locomotives of the type shown in Fig. 3 have been supplied by Messrs. Mather and Platt for working the line, each capable of developing up to 100 effective h. p., and of running up to 25 or 26 miles per hour. The armatures of the locomotives are constructed so that the shaft of the armature is the axle of the locomotive, Fig. 4; in this way all intermediate gear and all reciprocating parts are entirely obviated. The locomotives have a fixed wheel base and a motor is fitted on each axle, the axles not being coupled, but working quite independently. The current is conveyed from the collecting shoes through an amperemeter to a regulating switch, then to a reversing switch, thence to the magnets, and back through the framework of the locomotive to the rails, so completing the electrical circuit. The locomotives are fitted with Westinghouse automatic air brakes, and also a screw hand brake, and they are lighted from the working conductor. The train, when loaded, will weigh 30 tons, and it is intended that ten trains shall be worked on the line at one time.

Each train consists of an electric locomotive and three passenger carriages 32 feet in length from end to end of the footboard. The long passenger carriages are pivoted on two four-wheeled bogies; and the interior, which is divided by a door in the centre, contains seating for 34 persons. The enclosed portion is 2ɜ feet in length, the external overhang of the carriage platform being coupled up to the similar overhang of the adjoining carriage, and thus forming two open platforms between the three carriages. Upon each of these a guard travels with the train. These guards' platforms are protected at the sides by iron lattice sliding doors. The carriages are lighted by electric light, the current for the lamps being, in like manner, taken off from the conductor.

Each train carries its own reservoir of compressed air, sufficient for 40 stoppages, and as it arrives at the depot station of the line, recharges its air supply. The trains are also fitted with hand brakes, the stopping power being thus completely independent of the motive power.

In the generating house is the hydraulic machinery for supplying power to the elevators at the various stations. The cylinder of the ram is 2 feet in diameter, and the wrought iron flange-jointed pipes, which convey the water at a pressure of 1,200 lbs. to the square inch, are nearly a foot in external diameter. The engines which pump the water into them act automatically, being put in motion as the accumulator descends by loss of water at the elevators. At the end of this building is a locomotive repairing shop, with special appliances for lifting out or replacing the dynamos on the locomotives.

The limit of speed of the electric locomotive is 25 miles an hour. Ultimately, the trains will follow each other at three minutes intervals, but at the commencement of the traffic they will start about 7:30 a. m., and run every five minutes. The stations are lighted by gas; and for the water supply of the steam boilers which is taken from the water company's mains, there are two large tanks, one of 12,000 and the other of 25,000 gallons, as a reserve.

A "COMMERCIAL CABLE" FEAT.

THE Commercial Cable Co., of this city, has issued a tasteful reprint of an article from the San Francisco *Daily Report* of Sept. 27, 1890, showing how rapid had been the transmission by Commercial Cable, United Press and Postal Telegraph services of the news to Frisco of the Slavin-McAulliff prize fight in London. Owing to the speed attained, *Daily Report* extras were selling in the streets with a full account of the fight in just 17 minutes from the time of the dispatch of the final bulletin from London.

TANNING BY ELECTRICITY.[1]

BY A. BIGAUT.

An industry in which it would hardly be expected that electricity is designed to play a prominent part is that of tanning, yet the remarkable results which have been obtained leave little doubt in our minds that the electric current will soon be employed in this field on a large scale. The main object in applying electricity to tanning is to diminish the time heretofore required to convert the raw hide or skins into merchantable leather, a result effecting a reduction from several months to as many days. This is, of course, accompanied by an enormous saving in money in the interest on the value of the skins under treatment. At the present time two important tanneries are now working the electrical process; one of these, operated by MM. Brion and Dupré, in Paris, has been at work for over a year, while the other, the British Tanning Co., has been in operation for several months in London.

The application of electricity to tanning is not new. As far back as 1850 a currier by the name of Crosse invented a process in which he applied electricity. He was followed by A. Ward, of Lancashire, in 1860, who modified the Crosse process somewhat. And in 1861, in Paris, M. Rehn also attacked the problem. The role which he attributed to electricity in tanning was that under the influence of the electric current traversing the solution, the skins were opened and their tanning thus effected more rapidly.

In 1874, M. de Meritens also elaborated a process of electric tanning by which he was able to tan skins in 35 days, and this system is still employed in a tannery near St. Petersburg, having over 600 vats. Lucien Gaulard and Kresser also devised a process of this nature.

In 1887, MM. Worms and Balé, of Paris, invented a rapid tanning process by means of electricity. Their experimental factory, opened in 1887, was operated without much attention being paid to it for two years at Saint-Remyles, Chevreuse sur l'Yvette. The factory is said to be in commercial operation now.

1. *La Lumiere Electrique.*

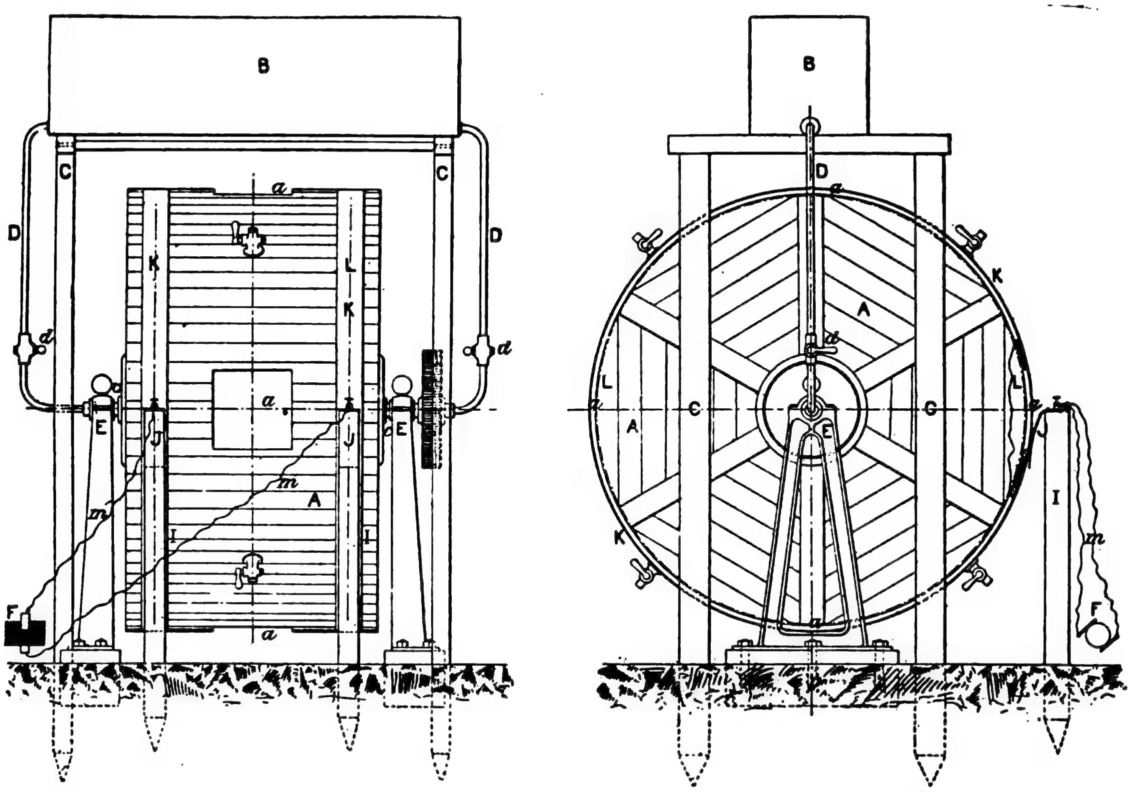
It is this process which is employed in the Paris tannery above mentioned, and in another at Bermondsey. Within a short time a large tannery will be put in practical operation at Longjumeau.

The Worms and Balê process differs from all preceding. In principle, it depends upon the fact that the tanning can be expedited:

First, by the agitation of the skins in contact with the tanning liquor;

Second, by the circulation of the electric current within the body of the liquid. This second fact had already been demonstrated by former trials, while the first is a well known method in tanning. It is the combination of these two processes which constitutes the originality and which ought *a priori* to increase the speed of tanning; and this has been demonstrated to be the actual fact.

The apparatus of MM. Worms and Balé, which permits of the combined agitation and action of the current, consists of a circular drum shown in the accompanying illustrations, Figs. 1 and 2, 13½ metres in diameter and 2½ metres deep, having a capacity of 1200 litres. The interior of the drum is provided with wooden pegs 30 cms. apart and 8 cms. in diameter, and 20 cms. long. The drum is also provided with four man holes *a*, closed by iron bars. The discharge cocks are placed between the doors.



Figs. 1 and 2.—The Worms and Bale Electric Tanning Apparatus.

Placed horizontally above the drum there is a large trough B containing 4,000 litres, and designed to hold the solution. At each end of the trough there is a tube which is connected with the large tube D which leads to the centre bearings of the drum so that the liquid can be introduced into the drum by the opening of the cocks *a*.

The electric current from the dynamo indicated at F is conducted by wires to two pillars I I on which two copper springs J J are fixed. These springs rub against two rings K K which entirely encircle the drum and to which are connected the electrodes L L. These constitute a pair of rings on the interior of the drum which encircle it in the same manner as those on the outside. The circuits can also be arranged to make the current pass from one bearing to another instead of by way of the rings.

In the establishment at Paris there are four drums arranged in the manner just described working continually. The dynamo employed is of the Gramme compound type. The voltmeter and the amperemeter are placed in circuit, and by means of a switch the direction of the current is changed every twelve hours so as to act equally on the electrodes. The above wires are slowly oxidized, but the renewal of the wires or copper bands is necessary only after a large number of operations.

The skins are prepared in the ordinary way, the hair taken off by lime, and they are then put into the drum with the tanning solution made of oak bark extract, and indicating 30° or 40° by the tan-hydrometer (3° to 4° Baumé). The drum receives 500 to 700 kilograms of skins and 1200 to 1500 kilograms of tan liquor, to which is added a little essence of terebenthine.

The drum is rotated at moderate speed while the current of the ampere meter is passed through at an E. M. F. of about 70 to 100 volts. The skins are subjected to the rotating movement, and the wooden pegs prevent them from attaching themselves to the inside of the drum ; and when they are raised to nearly a vertical diameter, they fall and are thus knocked about and beaten continually. During the operation the solution becomes deprived of the tannin, which is fixed in the skin. It is sometimes necessary to add new solution in order to bring the liquor back to its proper strength.

The rotation and electrolysis are continued from two to six days, according to the nature of the skin to be tanned. Goat and sheep skins only require about 24 hours for complete tanning. Calf skins require 48 hours, while cow, steer, and horse hides require from 72 to 96 hours, accordcording to their texture. During the operation the temperature increases but hardly ever passes 30° C.

As the drum is tightly sealed, a safety valve seems to be necessary to prevent an increase of pressure in the drum ; this has been provided in a very simple manner, but the pressure at any rate is only very small.

Thus in four days an operation is completed which ordinarily required 7 to 8 months, and which has been made possible without the addition of acid, and by the simple application of a physical agent which seems to introduce into the skin no other element than tannin. The results have shown that skins so tanned are not only stronger than those tanned by the old process, but that they gain considerably in weight by the process, while by the ordinary method the original weight is very little, if any, increased.

The operation which takes place may be considered to be, that the skins constitute the electrodes upon which the gases disengaged act. As pointed out by Prof. Silvanus P. Thompson, they are porous electrodes, susceptible of absorbing the gases produced by electrolysis. During the operation the liberation of gas is insignificant, so that the hides may be considered to act in the same way as the plates of an accumulator.

BREWER'S ELECTRIC RAILWAY CONDUIT.

ALTHOUGH the overhead system of conductors is now employed almost exclusively in the operation of electric railways, indications are not wanting to show that a good conduit system will soon find application in many cities in which public opinion is averse to the extension of overhead wires.

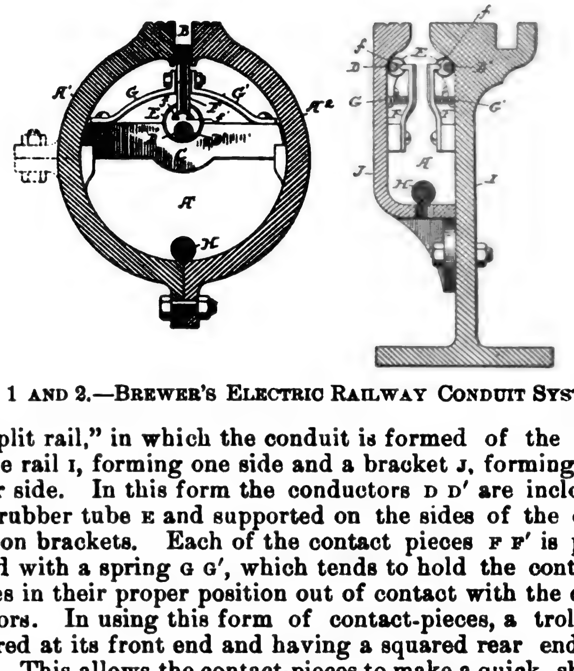
To meet the conditions of a railway conduit system, especially with reference to the thorough insulation of the working conductor, Mr. Wm. J. Brewer, of this city, has recently designed a conduit and method of running the conductors which present several interesting features.

One form of the conduit, which is illustrated in the accompanying engraving, Fig. 1, consists of two cylindrical sections of cast or wrought iron secured together by bolts at the lower end, leaving an open slot B between their upper portions. A brace C, extends across the conduit on the inner side, being connected to lugs. The brace serves to support the conductor.

The conductors consists of two rods D D′, insulated from each other. A single conductor with ground return can also be employed. This conductor is inclosed in a tube of insulating material, E, such as a rubber hose. At regular intervals contact-pieces F are inserted through the rubber tube, and when the conductor consists of two parts this contact-piece consists of two contacts *f f′*, insulated from each other and extending upwards into the slot, the ends being rounded. In order to support this contact-piece in the position shown, the springs G G′, are provided, which are mounted upon the cross-piece and secured to the contact-piece on either side, but insulated therefrom, and these springs normally tend to hold the contact-piece in its elevated position, so that the contacts *f f′* are out of contact with the conductor, except when the trolley arm presses down and effects the contact.

At the bottom of the conduit there is provided a wire rope or chain, H, which is used to clear out the conduit by pulling it to and fro, thereby loosening any dirt or rubbish which may fall in it and assisting its discharge from the conduit.

In Fig. 2 the same idea is applied to what may be termed



FIGS. 1 AND 2.—BREWER'S ELECTRIC RAILWAY CONDUIT SYSTEM.

a "split rail," in which the conduit is formed of the web of the rail I, forming one side and a bracket J, forming the other side. In this form the conductors D D′ are inclosed in a rubber tube E and supported on the sides of the conduit on brackets. Each of the contact pieces F F′ is provided with a spring G G′, which tends to hold the contact-pieces in their proper position out of contact with the conductors. In using this form of contact-pieces, a trolley, tapered at its front end and having a squared rear end, is used. This allows the contact-pieces to make a quick, sharp break of contact and prevents the establishing of an arc after the trolley has passed.

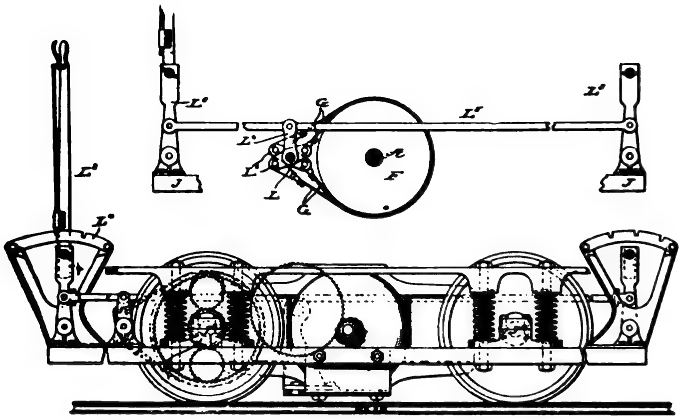
From the above description it will be obvious that the motor on the car obtains its current from the contact at the point where it happens to be at that instant ; and as the motor moves along, one contact is made and the other broken behind it. In this way the line remains completely insulated so that even a complete flooding would entail no leakage of current.

THE POWER PUBLISHING CO.

The above company which publishes *Power-Steam* has been compelled by the growth of its business to remove to new quarters, and it has accordingly located itself in the new *World* building on City Hall Square and Park Row. The company state that their subscription list for November is the largest on record, being the result of a steady and permanent increase, while the same onward tendency is shown in the advertising pages. Such an admirable paper deserves all its success. It is conducted with conspicuous enterprise and ability, and the practical nature of its interesting, well written articles renders it of the utmost value to all engineers who have in any way to deal with power problems or the handling of power machinery.

BELDING'S ELECTRIC RAILWAY CAR GEAR.

The difficulty of overcoming the heavy rush of current which occurs when an electric car is started from rest to motion has given rise to a variety of mechanism, the ob-



FIGS. 1 AND 2.—BELDING'S ELECTRIC CAR GEAR.

ject of which is to maintain the motor in constant rotation and to provide gearing for transmitting the motion of the armature in a gradual manner to the axles of the car. The problem has also been attacked by Mr. Warren S. Belding, of the Belding Electric Motor Co., of Chicago, who has recently patented the gear illustrated in the accompanying engravings. This consists of a sun and planet combination, by means of which the motor is kept in continuous operation, whether the car be moving or not, and which allows of reversing the car with the same continuous motion of the motor armature.

The manner in which this is accomplished will be readily understood. Supposing power to be constantly applied to the wheel C, in the same direction, then the wheel, the

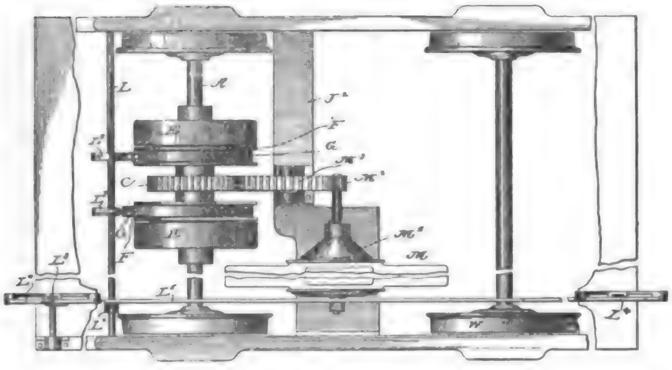


FIG. 3.—BELDING'S ELECTRIC CAR GEAR.

sleeve B, and both spur-wheels D D will rotate in unison without change of direction. The spur-wheel in the member of the mechanism at the right will rotate the wheels F² in an opposite direction, and since the latter mesh into the internal gear of the weeel E, the latter must be turned by the spur-wheel F², or the wheel E must offer sufficient resistance to cause the wheel F² to travel upon the internal gear and through the band-wheel F upon the sleeve B. When the brake-strap G does not engage the wheel F, the resistance of the latter is so small as to allow it to turn upon the sleeve B in response to the force exerted by the wheels D and E; but when the brake-strap G is drawn the wheel F is held rigidly and the wheels F² are no longer free to revolve around the internal gear of the wheel E. Consequently the wheel D acts directly upon the internal gear of the wheel E through the wheels F², thus rotating the wheel E and also the axle A.

Supposing the wheels C and D to be rotating in the direction indicated by the arrow in Fig. 5, then the wheels F² will rotate in the opposite direction, and the periphery of the latter will carry the wheel E in the opposite direction also, and since the wheel E is keyed to the axle A the latter will also be rotated in the direction opposite to the direction in which the wheels C and D are rotated. Looking at the gearing of the second member of the power-transmitting mechanism from the same direction, Fig. 6, it will be seen that the wheel D will rotate the wheel F³ in an opposite direction, while the latter will rotate the wheels F² in the same direction, and that the latter will not rotate the wheel E and axle A in the same direction as the direction in which the wheels C and D rotate. It is apparent, then, that the axle may be at rest while the wheel C is running in response to the extraneous power applied to it, and that if it is desired to rotate the axle and propel the car in one direction one of the band-wheels, F, is engaged, and that if it is desired to rotate the axle and propel the car in the other direction the other brake-wheel is engaged.

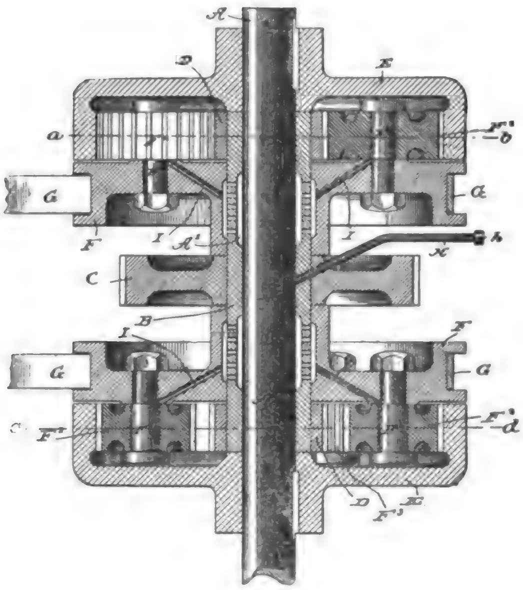

FIG. 4.—BELDING'S ELECTRIC CAR GEAR.

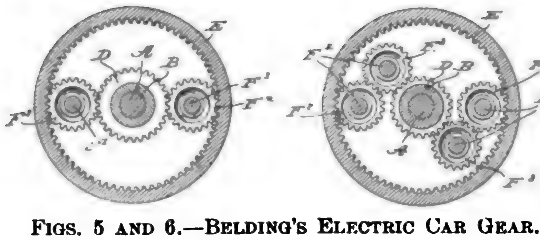
The ratio of the speed of the wheel C and the axle may be varied by varying the relative size of the wheels D and E.

Besides its function of driving the car, the motor may, in an emergency, be used also for braking it, so as to secure a sudden stop. This may be done by quickly reversing the lever L³, so as to apply the power of the motor against the motion of the axle. When the regular course of the car is in only one direction, the duplex mechanism is useful in quickly stopping the car, or in backing it; but when the regular course of the car is in only one direction the two members of the power-transmitting mechanism may be made to operate in the same direction, but at different speeds. Then one or the other of the members of the mechanism may be used, according to circumstances.



FIGS. 5 AND 6.—BELDING'S ELECTRIC CAR GEAR.

When there is a heavy load or a steep grade, the member of the mechanism giving the greater power may be used, while on a level or with a light load, the member of the mechanism giving the greater speed may be used.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. X. NEW YORK, NOVEMBER 26, 1890. No. 134

There is one radiant energy, which appears to us as "actinic," or "luminous" or "thermal" radiation, according to the way we observe it.—S. P. Langley.

ELECTRICITY IN MILL WORK.

IF it were not for the fact that so much of the energy of electrical engineers available in the motor department were devoted to questions of street car traction, we should see more attention paid to the great opportunities now presenting themselves in mill work for electric power distribution. The matter must, however, soon force itself upon the consideration of engineers, and we do not hesitate to assert that within two years the complete equipping of mills with motors will be one of the largest and most active fields of electrical work.

Such instances as already come under notice are very encouraging. In a recent address before the Boston Society of Civil Engineers, Capt. Eugene Griffin described a mill or factory plant where it had been estimated by competent engineers that with belting and shafting in the ordinary way from 30 to 50 h. p. would be required; and 15 h. p. additional was necessary for lighting. But, as an actual thing, the motors are delivering about 50 to 70 h. p., though the energy developed runs an average of only 17 or 18 h. p. for ten hours, owing to the immediate adjustment of the generating plant to the load, and the absence of long lines of idle shafting to be driven. A still more striking example has just come to our knowledge, worthy of widespread publicity. About a year and a half ago the Globe Tobacco Works in Detroit were furnished with an installation of seven Eddy motors; another has lately been added. The motors vary from 1 up to 15 h. p., and they aggregate 57 h. p. It appears that as the result of this equipment, in which the motors have been placed exactly where the power was wanted, and, as usual, under onerous conditions, the Globe Company are saving, according to their own statement, about 20 h. p. over the old style of transmission by shafting and belts. Nor is this all, for they say that they are lighting their factory, a large building, with incandescent lamps, at no perceptible additional expense. It may be remembered by some of our readers that in this installation it was ingeniously arranged that, if desired, the plant could switch its surplus current into the street incandescent mains, and while we are not aware that the plant has ever been called on to do this, the point should not be overlooked.

Here, then, we have an installation of 8 motors of not quite 60 h. p. with which a saving of 20 h. p. is cheerfully admitted by the users, while the lighting is, so to speak, "thrown in," and the attention and repairs are a minimum. Too much prominence cannot be given such cases as this as an example of what electricity can do for the mill. If this can be done in one mill or factory, it can be done in another.

According to figures accredited to a New England cotton mill engineer of high reputation, eight modern mills, with first-class shafting, showed an average per cent. of 28.7 of the horse power of that required for the whole load to be used by the shafting. In one instance, to drive the shafting alone took 36.1 per cent. of the whole horse power and in another 39.2. These are remarkable figures. With motors simply located so as to drive short independent lines of shafting on each floor, part of this waste would still have to be endured; but there is often the choice of coupling the motor directly to the machine it is to run.

It has long ceased to be a novelty for mills and factories to employ the electric light, and where they have the apparatus for the one service it should be easy to introduce the other. A singular episode occurred a month or two ago in an English mill, where, the regular motive power having broken down, one of the lighting dynamos was driven by its fellow as a motor, and being belted to the shafting kept the mill in operation. Perhaps incidents of this kind will help arrest attention on the flexibility of electrical distribution; and when there is added the economy illustrated so forcibly by the Globe Tobacco Works, the universal resort to electric power for mill work is not likely to be long delayed.

ELECTRIC TANNING.

THE number of arts in which electricity is now being brought into play as a useful adjunct is increasing at a rate which makes it evident that before long the electrical engineer will be a necessary and permanent employé of most manufacturing establishments. The marvels which electricity has already accomplished in the domain of metal working, are well known, and only recently we recorded the result of the greatly increased yield in agricultural products cultivated on ground through which the electric current had been passed. We were, therefore, thoroughly prepared to give credence to the remarkable results recently obtained in the tanning of leather by the

employment of the electric current. The new process, which we describe in another column, is based on sound theoretical principles, and the results obtained are, indeed, just what might have been expected. We have before us the results of tests recently made in this country, in which the process is about to be introduced, which show that, with the process of Messrs. Worms and Balé, 919 pounds of hides gave 1,278 pounds of leather in four days. The tests also show that 1,042 pounds of hides, subjected for the same length of time to the action of the revolving drum, but without the presence of the electric current, gave only 1,210 pounds of partly tanned hides. The saving in time possible by the new process, as well as the gain due to increase of weight, are evidently factors of great economical importance, and would appear to be sufficient to warrant the adoption of the process.

The daily press, in recording the new applications of electricity, as a rule, welcomes them as a new source of employment and profit, or of comfort to many. We therefore noted with surprise the appearance last week, in the New York *Herald*, of an article in which it was sought, in a clumsy way, to cast ridicule upon the new process, and in which the conclusion arrived at is, that the same results can be obtained in the four days, without the use of electricity. It is needless to point out that if such were the case, our enterprising tanners would hardly be likely to let hides lie in the vats for seven months when four days will suffice to accomplish the desired object. Our contemporary is usually accurate in its treatment of technical questions and it cannot afford to oppose with sneers and abuse well established facts, the force of which must make them felt in spite of opposition. We hope that the new process will receive a thorough trial in this, the greatest leather producing country in the world, and thus add another to the applications of the current that now greet us at every turn. We may add that we have carefully inspected the leather ourselves and have had it examined by experts of the highest reputation. It is impossible to resist the belief that the process is destined to be one of the greatest factors in modern tanning.

ELECTRICAL TESTING.

The history of the first twenty years of telegraphy in this country is one remarkable alike for the rapidity of growth of the industry, as well as for the impediments which beset it during that time. It will be within the memory of many of our readers that, in 1869, shortly after the accession of Mr. Wm. Orton to the presidency of the newly consolidated Western Union Telegraph Co., the services of Mr. C. F. Varley, the eminent English electrician were called on to bring order into the electrical chaos which then existed in the telegraph system. The results of Mr. Varley's investigation showed that one-half the wires on this continent were practically useless and that the office apparatus was of such a character as to seriously reduce the efficiency of the service.

It goes without saying that this deplorable state of affairs was due almost entirely to a lack of systematic testing, and the introduction of the latter in this country was immediately followed by a succession of brilliant improvements, as well as an enormous economy in operation.

While the lesson taught those in the telegraphic field has been well heeded, it was, unfortunately, forgotten or never heard of by many of the pioneers in the later fields of telephony and electric lighting; and it required the severe school of experience to teach these again that true economy can only go with a definite knowledge of the condition of the service, and that this can only be attained by systematic and continuous testing.

As a result of this, we have been glad to note the addition to the staff of numerous electrical companies of men charged with the electrical supervision of lines and apparatus, which had heretofore been allowed to run along in an uncertain way until early and very premature total failure made their renewal imperative. But there is still much room for improvement in this respect and many a position where a competent electrical engineer will find work cut out for him, and hence it is well for those who wish to become fitted for it to acquire the necessary training and skill.

It is with this object in view that we have begun an illustrated series of articles on practical methods of testing insulated wires and cables from the able pen of Mr. Herbert Laws Webb. Being himself actively engaged in the work he describes, Mr. Webb is able to place before his readers the practical methods used in everyday working, designedly leaving on one side the more refined and special methods which are, indeed, but seldom employed out of the laboratory. As Mr. Webb points out, the carrying out of such tests involves no great difficulty when the apparatus is properly set up and adjusted, and it is with the object of imparting such information as well as describing the methods of manipulation that the articles which we began in our last issue have been prepared.

The Artificial Light of the Future.

The superiority of the electric light, looked at from the standpoint of efficiency, is undisputed, but the fact still remains that the actual energy required to produce a given amount of light is far in excess of that theoretically necessary. How to diminish this disproportion has been the subject of much speculation, and the nature of the problem is admirably presented by Prof. E. L. Nichols in the paper read by him last week before the New York Electric Club. The present limitations of carbon as the light-producing medium are well defined, and other substances capable of withstanding high temperatures are brought forward. As Prof. Nichols remarks, "luminescence" by heat can never give us the best results in efficiency, but we believe that by the aid of electrical action in one form or another, results can be obtained more economically and conveniently than with any other method.

Sale of Bell Telephones.

It having been reported that Bell telephone instruments would be sold outright for private lines at $10 only, the American Bell Telephone Co. has positively denied the report. It is characterized as utterly without foundation. The company will, as heretofore, adhere to the system of rental.

LOW SPEED MULTIPOLAR DYNAMOS AND MOTORS FOR CONTINUOUS CURRENTS.

BY FRANK A. PERRET.

THE many practical advantages of a lower rate of speed in dynamo electric machinery have long been recognized, yet until recently few attempts have been made to secure it. The wide-spread use of the electric motor has, however, rendered low speed a feature of great importance, in that it so greatly simplifies the application of the machine to all classes of work, in most cases obviating the necessity of counter-shafting or similar speed-reducing mechanism.

The writer is aware of a prevailing opinion that serious difficulties are encountered in the attempts to manufacture this class of machines on a commercial basis, but believing the difficulties to be surmountable, he devoted several years to a careful study of the subject, with the result that he designed a type of machine in which he believes the desired end is attained without the introduction of any element of danger or the sacrifice of a single feature essential to a thoroughly practical machine.

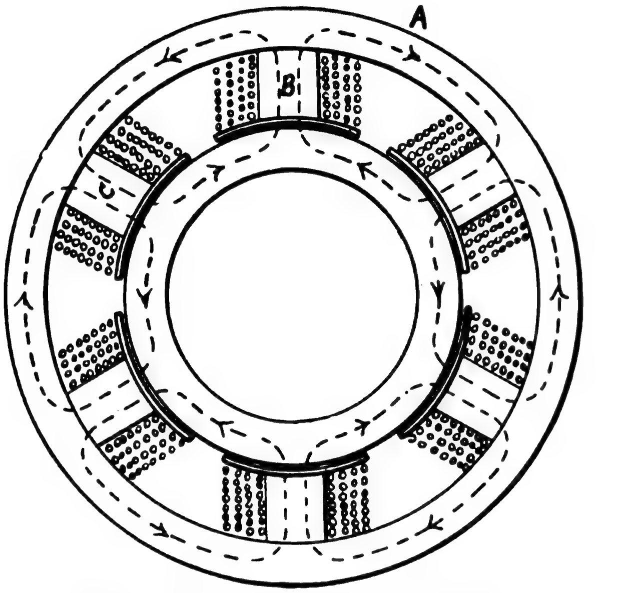

FIG. 1.—ORDINARY MULTIPOLAR FIELD.

In the light of this experience it is proposed to consider briefly some of the principles which govern the action of multipolar machines, and to demonstrate that the obstacles which have heretofore stood in the way of low speed, may be, and have been, overcome.

The prime function of an armature conductor is the generation of an electromotive force, the value of which is proportionate to the number of magnetic lines of force cut by it in a given time. Now, the number of lines cut per second is dependent upon two factors, (1), the total number of lines of force in the magnetic circuit, and (2), the number of times they are cut per second. As our aim is to generate a given E. M. F. at a *lower* speed than is usual, it is evident that the quantities in either or both of the above factors must be increased. In the case of the first we are limited by the saturation point of iron which prevents our indefinitely increasing the strength of the magnetic circuit without adding abnormally to the weight and size of the machine, and even were it possible to do this, an increased exciting current would be required, which would detract directly from the total efficiency. We turn then to the second factor and, paradoxical as it appears at first, it is here we find the solution of the problem. How are we to cause an armature conductor to cut a given number of lines of force a greater number of times per second without increasing the speed? In the ordinary two-pole machine the armature conductor crosses the magnetic circuit and cuts all the lines of force twice during a complete revolution, viz., where they enter the armature core at one pole and where they leave it at the other. Now, if we so dispose the magnetic circuit as to cause the lines of force to enter the armature core at one point, to leave it at another, to *enter it again at a third point and to leave it at a fourth*, it is obvious that the conductor will cut all the lines at four points in each revolution, and that it will therefore generate the same E. M. F. at one-half the original speed. If we increase the number of poles to six, we shall obtain the same effect at one-third the speed, etc., etc. This, then, is the principle of construction by which we secure low speed.

It should be noted that we do not increase the number of lines of force in the magnetic circuit, we do not add to the turns of wire in series on the armature, we do not increase the amount of either copper or iron in the entire machine, but we simply cause the armature conductor to cross the magnetic circuit as often in one revolution as it ordinarily does in two or three revolutions, as the case may be. The writer wishes to emphasize these points as there seems to be some misunderstanding in regard to them. We do not *wind an armature to run slowly*, but we design the machine for low speed. The resistance of our armature is no higher than that of a high speed machine of the same power, its current capacity is not reduced; in fact, as we shall see later, it is increased. The efficiency is no lower, the regulation no less perfect, and the weight and bulk no greater. We see then that in theory the multipolar machine is perfect; consequently if any difficulties have been encountered in its practical operation they must be due to some faults of construction, to a consideration of which the attention of the reader is now invited.

If we take as an example a motor having a six-pole field, and imagine the same in action, we see that the distribution of potential is such as to form the equivalent of three ordinary armature windings on the one ring and connected to the commutator, which has three times as many segments as that of a two-pole machine. Each of these windings, *i. e.*, the wire lying under one pair of poles, has exactly the same number of turns as an armature of a two-pole machine but of smaller wire, and carries but one-third of the total current, the three acting together in multiple. This being the case, any relative difference in the strength of the field magnet poles will cause an unequal distribution of potential and current in the armature. This is, in my opinion, the most important point to be considered in the designing of such machines, as any inequality is sure to cause trouble.

In a bi-polar machine there is but one path for the lines of force, which circumstance insures equal poles, but in the multipolar type, as ordinarily constructed, a variation in the magnetic conductivity of any part of the circuit will cause an inequality.

Fig. 1 represents a form commonly given to multipolar fields. It will be seen that an internal blow-hole, or hard spot, or other imperfection in the casting at A, would choke some of the lines proceeding from B, and they would therefore flow through C, and cause a difference in the strength of the poles. Cast iron should therefore be excluded from the magnetic circuit, there should be no joints, and the number of magnetizing coils should be as small as possible.

Fig. 2 is a diagram of the magnetic circuit of the machine designed by the writer. In this construction there are but three magnets, each being isolated magnetically from the others excepting through the medium of the armature core, and completely isolated from the frame-work of the machine. They are formed of plates of soft sheet iron, which are punched to the required shape and strung together on non-magnetic bolts by which they are secured to their supports. A single magnetizing coil forms two salient poles, and as each magnet is built of a large number of plates a uniform magnetic conductivity is secured. By this method of construction all danger of any inequality in the strength of the poles is avoided, and a magnetic circuit without joints and of the lowest possible resistance is secured. It is understood, of course, that in all cases the number of ampere turns on each magnet must be equal.

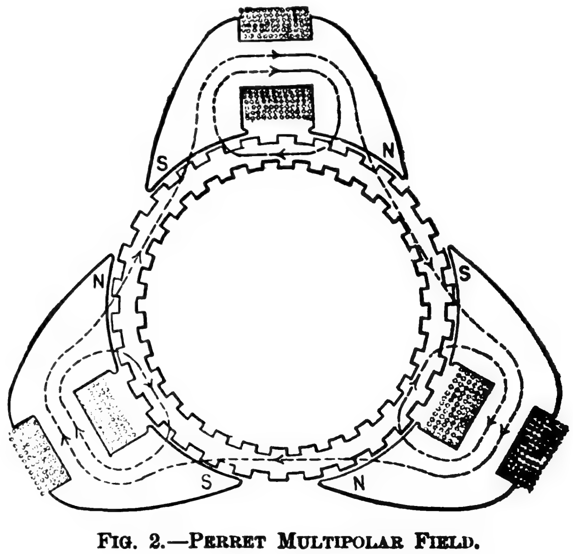

FIG. 2.—PERRET MULTIPOLAR FIELD.

In proportion as we decrease the "feet per minute" we increase the "lbs. raised," or, in other words, the mechanical effort or torque is greater in a low speed than in a high speed machine; extra pains should therefore be taken to secure a substantial mechanical mounting for the armature upon the shaft, and also for

the wires upon the core. The armature is, therefore, built up on eight insulated steel bolts, the ends of which are secured to non-magnetic spiders, which in turn are keyed to the shaft. The wires are wound in longitudinal channels on the periphery of the armature core which holds the coils rigidly in place and entirely prevents that minute shifting of the wires which certainly is the cause of so many "break downs" and "burn outs" in armatures. The driving force in a motor and the resisting force in a dynamo is exerted by the armature conductors, and we should always provide a positive mechanical connection between them and the core; friction does not suffice. The importance of this point is fully understood by Kapp, who writes: "In many machines the friction produced by the binding-hoops is alone relied on to carry the wires through the field; but experience has shown this to be insufficient. Even if the wires are not bodily torn off the armature by the magnetic resistance of the field, they shift and work on the surface of the core; and it is only a question of time when the insulation will be destroyed, and the machine break down."

We have a choice of two methods of coupling the armature circuits together in multiple, one of which is by the use of six brushes distributed around the commutator 60° apart, three negative and three positive, and the other consists of a system of cross connections in the armature or commutator which connects those coils which are simultaneously undergoing the same induction; these in a six pole machine are situated 120° apart. By this means a single pair of brushes suffices, and these bear on the commutator at points diametrically opposite, exactly as in a two-pole machine. This method is preferred when copper brushes are used, and I have in use a simple system of cross-connections at the back of the commutator, in which all danger of short-circuiting is avoided; but the carbon brush is so peculiarly adapted to the method first described that it forms one of the simplest and most reliable means of commutation that can be devised. The high resistance of the carbon brush, as ordinarily constructed, has prevented its universal adoption, but the construction of this machine permits the use of three pairs of brushes, each pair carrying but one-third of the total current, and the resistance is greatly reduced by reason of the increased contact surface.

In a two-pole machine the armature current is divided equally between two circuits, while that of a six-pole machine splits into six. This the writer considers in most cases an advantage, as the current carrying capacity is increased by reason of the greater surface exposed to radiation, and the machine will consequently bear a greater overload without injury while the wire is not so large as to be unmanageable. In many machines of the two-pole type a stranded armature conductor must be used, because a single wire would be too stiff and would heat too much; in a multipolar machine these troubles are avoided.

A great deal has been said and written in respect to the difference of potential that should be allowed to exist between adjacent commutator segments, some writers having advanced erroneous opinions on this point to the disparagement of multipolar machines. One tells us that 10 volts should be the limit because "10 volts will just form an arc," while another puts the limit at 19 volts and gives the same reason.

Now, an arc has to be started or "drawn" and the only time this can happen is when the brush connects two adjacent bars as they pass under it. But this only takes place at the so-called neutral points where the difference of potential between adjacent bars is almost nothing. Theoretically this difference of potential is simply the product of half the total current and the resistance of the coil connected to the two bars. We see, therefore, that we should not take for a basis of calculation the *average* difference of potential between adjacent bars, for the reason that the E. M. F. of each coil is continually varying from zero to maximum and down to zero again. A very clear description of this action will be found in the fourth chapter of S. P. Thompsons' "Dynamo Electric Machinery," together with the methods used in determining it, and I commend a perusal of this to the writers referred to.

In a machine wound for 220 volts and having 22 coils acting in series, we do not find a uniform difference of potential of 10 volts between adjacent commutator bars, but those coils which are passing the poles are generating 15 or 20 volts, while those in the neutral zone are generating practically nothing. In some of the most widely used closed coil machines in this country the average difference of potential between adjacent segments is far greater than the limits given by the above mentioned writers. In one of these it is 27 volts, in another 50 volts, and in others it is still higher, yet these machines give no trouble whatever. Let me not be understood to favor the use of a small number of commutator's sections, I simply wish to show that no one is limited to 10 or to 19 volts, average potential difference between adjacent bars.

In the machines of my own design, which I have partially described, the number of sections in the commutator is 96, of which 16 act in series. At an E. M. F. of 220 volts they average, therefore, 13¾ volts each and at 500 volts total E. M. F. they will average 31¼ volts.

As bearing upon some of the statements which I have made, I present the following details of my 10 and 20 h. p. machines, which fairly represent them all:

10 h. p. 220 volt motor.
Speed, 600 revolutions per minute.
Weight, 900 lbs.
Resistance of armature, .19 ohm.
Resistance of shunt, 175 ohms.

20 h. p. 110 volt dynamo (compound).
Speed, 600 revolutions per minute.
Weight, 1,300 lbs.
Resistance of armature, .029 ohm.
Resistance of shunt, 26 ohms.
Resistance of series coil, .007 ohm.

It will be seen that a low speed multipolar machine is not necessarily a heavy one, but that on the contrary it may be made very light. The writer has recently built several 25 h. p. series wound motors which weighed 1,300 lbs. each and ran at a speed of 500 revolutions per minute. If one of these were so wound as to run at 1,000 revolutions per minute, it would develop 50 h. p. and weigh only 26 lbs. per h. p. For traction purposes these motors are designed to run as slow as 450 revolutions per minute and weigh about 70 lbs. per h. p.

In regard to their practical operation, I will simply say that the first machines which were constructed a year ago have been in constant and satisfactory use ever since, and they have proved themselves to be in every respect the equals of the high speed machine.

ON THE THEORY OF COMPOUND WINDING FOR CONSTANT POTENTIAL.[1]

BY DR. LOUIS BELL.

I wish to preface this paper by stating that there is in it nothing revolutionary, nor any radically novel attempt to treat a problem that has already been handled by more skillful hands than mine. It is simply an effort to bring the theory of compound winding to a practical basis, indulging in no complicated formulæ and introducing no constants that cannot be conveniently determined in practice. To this end I shall consider the subject synthetically rather than analytically, starting from the plain shunt winding and considering those terms which must be introduced to take account of the failure of shunt winding to give constant potential. I do not think that compound winding should be considered as anything more than a method of improving a shunt machine already well designed; it should certainly never be called upon to avoid the evil effects of bad design.

For the systematic treatment of the subject I would introduce the following notation, which differs slightly from that most often employed, but is convenient for the purpose in hand.

Let C_x, represent the current on the line;
C_s, the curret in the shunt coils;
R, the resistance of shunt coils;
r, the resistance of armature and series coils combined;
E, the E. M. F. of the machine running light;
e, the fall of potential due to armature resistance;
N, the number of convolutions in shunt coils;
n, the number of convolutions in series coils;
m, the number of convolutions on armature;
a, b, c, the three terms of n;
l, the angle of lead;
q, the magnetic resistance of machine on open circuit;
q_x, the magnetic resistance of machine at full load, and
p, the value of q_x divided by q.

I shall consider especially the long shunt arrangement, though, as will be seen later, the short shunt leads to practically the same results.

The first and obvious cause of fall of potential at the terminals of the machine is due to the fact that the armature has a resistance; as the current increases a certain amount of potential is absorbed in the armature, and consequently the available E. M. F. at the terminals fall. The amount of decrease is evidently proportional to the resistance in the armature and the current through it

$$e = r\,C_x\,.$$

To compensate this loss we must furnish an increase of induction sufficient to produce e additional E. M. F. If the field magnets and the armature core were quite unsaturated, that is, if we could neglect the change in permeability, we should simply increase the total ampere-turns to an amount sufficient to compensate the fall in potential. Let a be the series turns capable of producing this at full load, neglecting change in permeability, then

$$a = \frac{Nr}{R}\,,$$

But the permeability decreases as we put on this additional induction. The magnetic resistance, q at the start, will have increased to a certain other value q_x. We must therefore increase

1. A paper read before the American Institute of Electrical Engineers, New York, Nov. 18, 1890.

the number of series turns to take account of this added resistance, and we have

$$a = \frac{Nr}{R} p.$$

It will be observed that this quantity does not have to be multiplied by the coefficient of leakage because we have simply reduced the shunt turns to equivalent series turns, and consequently have already included it. This formula will be at once recognized as practically equivalent to that given by Thompson in his well-known book, and at this point Thompson drops the investigation, merely mentioning incidentally some of the other causes which necessitate compounding. Thompson's formula:

$$\frac{Z}{S} = \frac{r_s}{r_s + r_m} \times \frac{q_1}{q_0}$$

is not quite the same as mine for the reason that while his q_0 is proportional to the permeability when there is no external current, his q_1 is proportional not to the permeability at maximum current, but to the mean permeability between no load and full load. Hence if Z is taken as the number of shunt turns required to give the desired potential on open circuit, Thompson's formula will inevitably give too few series turns for the reason just mentioned, if for no other. But since by adding series turns the magnetic resistance is increased the shunt winding which produces E volts on open circuit will not do so at full load. Additional series turns must then be employed to compensate for this and since the change in shunt ampere-turns must be from NC to NCp, the number of series turns to be added to compensate for the decreased effect of the shunt will be

$$b = \frac{NE}{R}(p - 1).$$

This term also includes C_s coefficient of leakage for the same reason as before.

It will be noticed that both a and b include the quantity p, and here is met the principal difficulty in affecting the compounding. It is my purpose to show that this quantity p can be obtained from known data with sufficient accuracy for the purpose in hand. It will evidently be a quantity little in excess of unity and in practical machines may range from 1.05 to 1.50, although in certain cases it may even exceed the latter figure. Thompson gives the case of a certain Siemens compound machine in which p would be over three. This, however, must have had a very insufficient amount of iron in the magnets or the armature core, or both. We fortunately do not have to deal with dynamos of such bad design very frequently. Provided we have known enough about the iron to be used in a given machine to design the shunt winding intelligently, we shall also know enough to design the compound winding. If we have at hand the characteristic curve of a similar shunt machine p can be determined very easily from it. I give herewith the data for the Manchester machine described by Dr. Hopkinson. I have simply taken the apparent permeability from his characteristic curve.

When magnetizing force	equals	1,000,	$\frac{\text{induction}}{\text{magnetizing force.}}$	equals	470
"	"	"	2,000	"	"	465
"	"	"	3,000	"	"	460
"	"	"	4,000	"	"	460
"	"	"	5,000	"	"	460
"	"	"	6,000	"	"	451
"	"	"	7,000	"	"	443
"	"	"	8,000	"	"	425
"	"	"	9,000	"	"	400
"	"	"	10,000	"	"	377
"	"	"	11,000	"	"	353
"	"	"	12,000	"	"	333

If the permeability curve of the iron is known even approximately we can obtain p from it quite readily. In Plate 1, let a b be the permeability curve. The permeability at no load corresponds to the point d, that at full load to the point f. Now lay off the ordinate d e so that the ratio between d e and c d equals the ratio between the iron resistance and the air resistance of the proposed machine, then lay off from the point f the ordinate f g equal to d e, and draw g h. Then the ratio of the lengths h c and e c corresponds to the quantity p required. Plate 2, drawn from Hopkinson's figures, gives numerically the change in permeability for cast iron. The figures relating to the Manchester machine were, of course, for wrought iron cores and cast iron poles. It is thus evident that a rather close approximation to the value of p can be made if we know anything about the iron that we are going to use. Now as we shall see later, and as is indeed evident at the start, a and b are of about the same order of magnitude. I do not think that b will ever be negligible in a practical machine unless a is also negligible, and there is, therefore, little need for compounding. When the magnets are anyway near saturation b will be much larger than a, but both a and b combined will not give the proper number of series turns for constant potential unless the armature is run with no load, and therefore produces no demagnetizing effect. The approximate damagnetizing effect of the armature has been investigated by Hopkinson and is as follows:

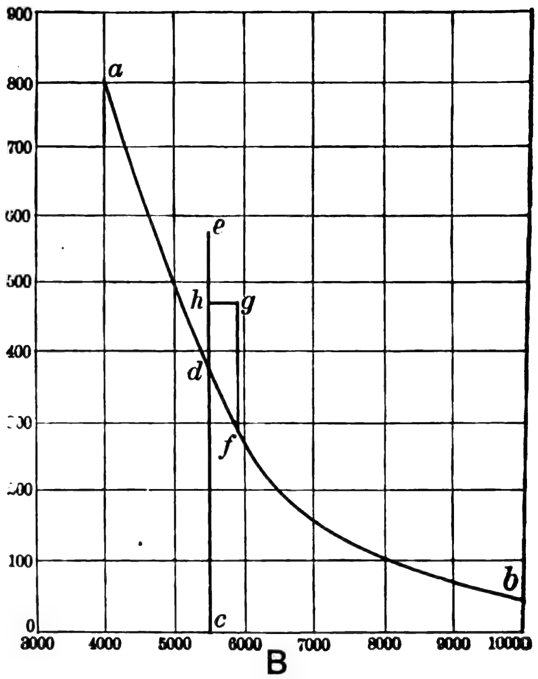

Plate 1.

$$4 n \bar{C} \frac{m}{2} \times \frac{2l}{\pi} = 4 l m C.$$

In other words, it is due to the convolutions included in twice the angle of lead. For constant potential we must add then c turns in series equal

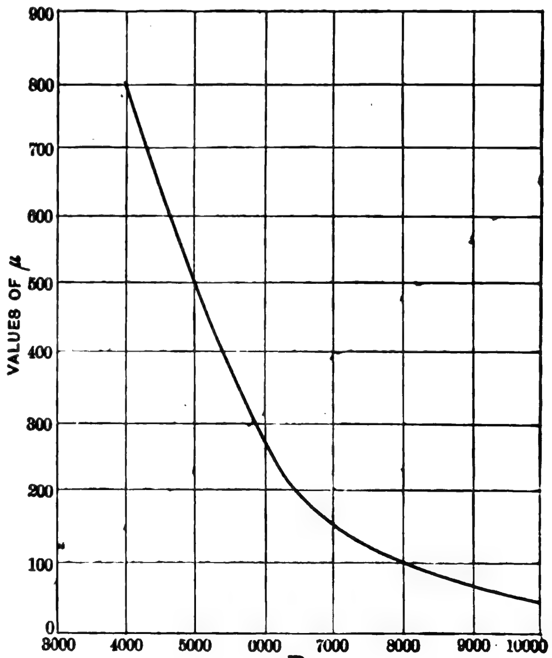

Plate 2.

$$v m \frac{l}{\pi}.$$

It is evident at once that a change in lead will effect the compounding; an increased load will cause the machine to under-compound, a decreased load to over-compound. As, however, the amount of distortion in the field depends largely on the shape of the extremities of the pole pieces, the above uncertain factor in

shunt is allowed to increase, the change in resistance will decrease the relative power of the series coils, and the machine will under-compound.

It now only remains to glance at some of the formulæ heretofore given. That of Thompson I have already incidentally discussed. That of Frölich (perhaps the best we have had) should receive mention here. Frölich takes account of the change in permeability by introducing a quantity f. Like Thompson, his formulæ involve two pints of saturation. It should be said here that there is no special black magic about the half saturation point of a dynamo, any more than about the three-sevenths or the seven-thirteenths saturation point. In very many cases it happens to be about the point at which the machine is used. Kapp, in his well known and excellent book, takes account of the change in permeability with a fair degree of approximation, by the use of his tangent function.

All these attempts at the proper theory of compounding depend, like the one which I have just presented, on forming some sort of an estimate on the change in magnetic resistance of a dynamo, due to adding a certain amount of induction. Without some approximate method of finding this quantity, the problem is indecompounding can often be gotten rid of by a little care in designing the poles.

It is obvious that the term c is to include the coefficient of leakage. Uniting now, the three terms, a, b and c, we have finally, as the completed formula for compound winding, the following:

$$n = p\,\frac{Nr}{R} + \frac{\frac{NE}{R}(p-1)}{C\,x} + v\,m\,\frac{l}{\pi}.$$

It now may be interesting to see how well this formula applies to practical machines. I regret to say that I have been unable to get full details of any machine which gave exact compounding, but I have obtained an assortment sufficiently large to show in a general way the applications of the formula.

Machine No. 1, 110 volts, 8 amperes, over-compounded 2 volts. For this small machine take p equal to 1.2. Applying the formula, a equals 14, b equals 44, c equals 15; total series turns by formula, 73; actual number, 90.

Machine No. 2, 110 volts, 3 amperes, over-compounded 3 to 5 volts. a equals 2, b equals 7, c equals 7; total series turns by formula, 16; actual number, 28.

Machine No. 3, 500 volts, 20 amperes. p equal to 1.1, a equals 3, b equals 15, c equals 14; total turns by formula, 33; actual number, 60. Machine over-compounded 3 to 5 volts.

Machine No. 4, 110 volts, 200 amperes, over-compounded 5 volts. p equals 1.05; lead rather large. a equals 2, b equals 2, c equals 5; total turns required, 9; actual number, 12.

Machine No. 5, 500 volts, 60 amperes. p equals 1.05, over-compounded about 7 per cent. a equals 3, b equals 5, c equals 4; total, 12; actual number, 32.

Machine No. 6, 500 volts, 90 amperes. p equals 1.05; a equals 3, b equals 4, c equals 4; total turns should be 11; actual number, 19. Machine over-compounded like the former.

Machine No. 7, 500 volts, 150 amperes. p equals 1.05; over-compounded 7 per cent. a equals 3, b equals 3, c equals 3; total 9; actual number of turns, 28.

Machine No. 8, 100 volts, 30 amperes. p equals 1.1, a equals 13, b equals 46, c equals 25; total 84; actual turns, 56. Machine over-compounded about 2 volts, and the shunt winding did not bring the potential up to the 100 volts intended.

These are merely rough figures, obtained without the use of even the permeability curve of the iron—simply by estimation from permeability curves at hand. It will be seen, however, that all the over-compounded machines got from the formula too few series turns, while the under-compounded machines gave too many. I think that the discrepancy is of about the right order of magnitude, although we cannot verify it accurately without the curve of the iron.

It remains to consider some few further points regarding compounding. If the winding is designed to give the potential at practically no load and at full load, it necessarily follows that at some point between the potential will rise; for, while the magnetizing force changes along a line, the magnetic resistance changes along the corresponding curve between the same points.

An approximate idea of the amount of irregularity in potential may be gained from Fig. 1. Connect in this diagram d and f by a straight line. From its middle point drop an ordinate upon the axis. The length intercepted between the straight line and the permeability curve then gives the error in compounding by comparison with the total change of magnetic resistance.

It should be noted that the formula I have given determines the compound winding for a given assumed potential produced by a shunt coil alone; therefore, if the machine is to be run at a slightly different speed from that at first intended to produce this given voltage, the compounding is still correct, for it pertains to the voltage rather than to the speed. If the speed of a correctly compounded machine be raised and the current in the shunt kept constant, it will tend to over-compound. If the current in the terminate, and the special thing which I have endeavored to show is that from the data already at hand about iron, we can form a sufficiently close estimate of the value of the coefficient p, without either knowing the characteristic of the machine, or indulging in endless approximations. I hope that some practical designer will look into the values that p takes in his machines, and I believe that it can be readily enough obtained to permit of quite accurate compounding, by the use of the formula I have given. The introduction of the terms b and c I regard as important. Their existence has been well known, but I do not think they have received the attention that I have endeavored to show they deserve.

THE ARTIFICIAL LIGHT OF THE FUTURE.[1]

BY PROF. EDWARD L. NICHOLS.

THE growth of electric lighting forms one of the most brilliant chapters in the history of invention. The record is one of which the electrician has reason to be proud. It is a record of advance following advance in our means of generating current and of transmitting it. It is the record of the evolution of the arc lamp from the first crude forms to the perfectly regulated lamp of today. It is the record of the development of the incandescent lamp. Throughout it all we note with wonder that the perfecting of 10,000 details of construction has gone hand in hand with ever diminishing cost of production.

As we review the history of the electric light, however, we

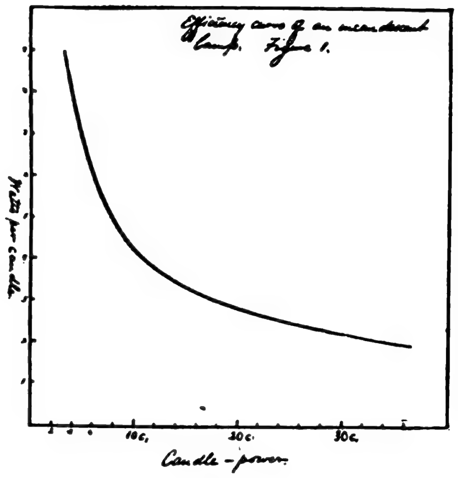

FIG. 1.

find that in two respects there is less cause for congratulation. When we come to consider the quality of the light produced and the efficiency of the apparatus as a light-making machine, we find that the incandescent lamp of to-day produces the same quality of light which the earliest examples of its type were capable of giving. We find, however, that its light differs but little from that obtained by burning oil and gas, which, in turn, in spite of all the improvements which have marked the growth of artificial illumination, is almost the same in quality as that which the Eskimo obtains from the crude blubber of the whale, or which the dweller in the log cabin on the frontier may get from his home-made tallow dip.

It is true that the efficiency of the incandescent lamp has gradually risen from five to three watts per candle, but those who have had occasion to trace the discouraging life curves of such lamps know how little real progress the change implies. We start a well manufactured lamp at any temperature we please, provided that we do not pass a certain limit, beyond which the life of the lamp would be too seriously curtailed. The initial efficiency may be made as large as we please, within that limit; but it is only a question of a few days or hours when the lamp will have dropped to the dead level of mediocrity, the five watt level which seems to mark the confines of permanency in the case of incandescent carbon.

When we take a lamp and raise its electromotive force step by step, measuring the current, voltage and candle-power at each stage of the experiment, and plot the curve which expresses the relation between the energy required and the light produced, we are gratified at the marked rise in efficiency which follows each slight increase in the temperature of the filament. (Fig. 1.) That rise of temperature, however, means shortening of the life of the

1. Read before the New York Electric Club, November 20, 1890.

carbon, is well known. Mr. John W. Howell, in a valuable paper read before the American Institute of Electrical Engineers,[1] has given us abundant data upon that point. Unfortunately, rise of temperature means much more than that. I will venture to show you a few life curves recently obtained in the laboratory of Cornell University. These curves enable us to see at a glance what happens during the curtailed existence of a lamp which is forced to undue brilliancy. I introduce them because they indicate very definitely the nature of the difficulties which confront us when we endeavor to increase the efficiency of an incandescent lamp by raising its temperature.

In the first instance, a lamp was started at the candle-power indicated by the maker, and was held at constant voltage by means of the current from a storage battery. The initial candle-

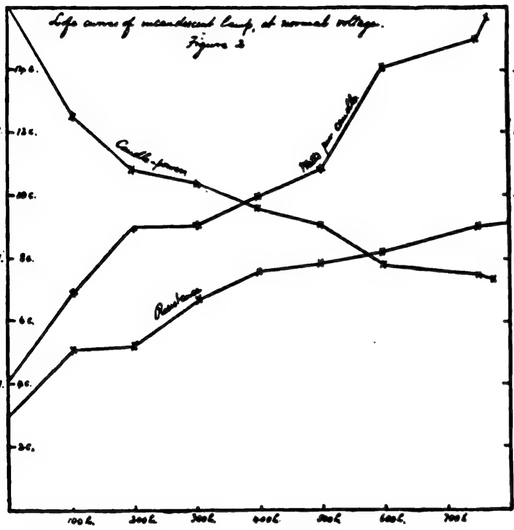

Fig. 2.

power was 16, which was obtained at the expenditure of 3.015 watts per candle. Measurements of electromotive force and current were made at intervals of about 10 hours, during the 800 hours that the lamp lasted. The candle-power was redetermined at intervals of about 100 hours. The voltage never rose more than 0.65 volt above its initial value, and then only for a short time. The average electromotive force of the entire run was 0.40 volt below the initial value. The record of this lamp is contained in Fig. 2. It represents an individual case and not the average obtained from many lamps, but it is typical of the results which have been obtained with many. The characteristic features are rapid, followed by slower falling off in candle-power, the decrement amounting finally to more than 50 per cent., and rapid, followed by slower, falling of efficiency, to a final value of 5.75 watts per candle. These changes were accompanied by continuous and marked increase in the resistance of the filament.

If it be asked whether this individual case represents a state of affairs common to all incandescent lamps, I can only say that in my experience, which is certainly much less extensive than that of some others, I have known of no class of lamps, the performance of which did not agree approximately with that indicated by these curves. Mr. W. H. Pierce,[2] who described extended tests of the initial and average efficiency of incandescent lamps in a paper read before the Institute of Electrical Engineers some time ago, recorded no exceptions to this rule of decreasing candle-power and efficiency with time.

This falling off in candle-power exhibited by lamps maintained at constant voltage can be met by a procedure not easily applicable, perhaps, in commercial work, but readily carried out where the object in view is simply to study the behavior of the lamp under unusual conditions. The method consists in raising the electromotive force at short intervals of time by amounts sufficient to restore the candle-power to its normal value.

The results of such an experiment performed upon a lamp precisely similar to that from which the curves in Fig. 2 had been obtained, are depicted graphically in Fig. 3. Under this treatment the life of the lamp in question was not quite 100 hours. The total rise in electromotive force during the test amounted to about nine volts; the efficiency decreased from 3.118 watts per candle to 3.468 watts per candle. The resistance of the filament rose from 221.6 to 234.8 ohms. During the first 50 hours the changes were slight, then occurred a sudden increase of resistance, accompanied by marked rise in electromotive force and in amount of energy consumed.

1. John W. Howell: *Transactions* of the American Institute of Electrical Engineers, vol. v, p. 237.
2. W. H. Pierce: *Transactions* of the American Institute of Electrical Engineers, vol. vi, p. 298.

The life history of the incandescent lamp at still higher temperatures does not differ essentially from that which we have just been considering, but the changes in question go on much more rapidly.

In Figs. 4 and 5 are recorded the performances of two lamps which were similar to those from which the curves in Figs. 2 and 3 had been obtained. The first of these (see Fig. 4) was started at 57 candles. It was maintained at constant voltage for 11 hours and 30 minutes when it went out. During its brief life the candle-power fell to 24.6c. and the watts per candle increased from 1.58 to 3.09. The loss of candle-power during the experiment was 55 per cent., an amount which corresponds very closely with the loss suffered by the first lamp tested during the 800 hours that it lasted. In the case of the other lamp (see Fig. 5), the initial candle power (64 candles) was maintained throughout. Its life under these circumstances was 140 minutes, during which short period it had been found necessary to raise the electromotive force from 114.08 volts to 129.53 volts. The efficiency of the lamp fell, meantime, from an initial value of 1.33 watts to 1.677 watts at the end of the first hour; then more and more rapidly to 1.945 watts at the end of the test.

The conclusion to be reached from these data, and from the great mass of experimental results which has accumulated since the incandescent lamp has become an object of investigation, is only too evident. The efficiency of an illuminant in which carbon is the glowing material, is a function of the temperature. It appears that the incandescent lamp is fairly stable only at temperatures for which its efficiency does not exceed about five watts per candle. We have just seen what occurs when one attempts to maintain lamps at degrees of incandesence corresponding to a much higher temperature. It is, perhaps, not possible to point out with perfect definiteness, all the causes that are at work to reduce the candle-power. The black coating which gradually forms on the interior of the lamp-bulb intercepts more and more of the light from the filament as the age of the lamp increases. The growth of this film and its power of absorbing light have recently been carefully studied by two of my advanced students, Messrs. B. E. Moore and C. J. Ling.

The life curves which I have just shown you were made by them as a necessary part of their investigation of the loss of light due to the opaque film, and I will venture to take from their work, as yet unpublished, the results which they have obtained in the case of the lamp to which the curves in Fig. 2 refer. These results are given graphically in Fig. 6. They show the amount of light of each wave length of the visible spectrum which the coating on the interior of the bulb absorbed. The measurements were made after the lamp had been in operation 100 hours, 200 hours, 400 hours and 800 hours. In the diagram, abscissae are

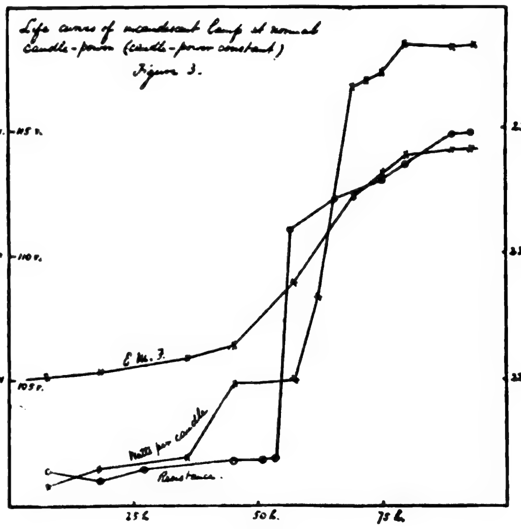

Fig. 3.

wave lengths and ordinates show the amount of light transmitted by the lamp bulb at the above mentioned times, in terms of the amount which the bulb allowed to pass before the coating began to form. You will see by a glance at these curves that the absorbing power of the film was very nearly uniform throughout the spectrum, so that the blackening of the lamp had no appreciable effect upon the light which it emitted; also that the absorption at the end of 200 hours was considerably more than half as great as that at the end of 800 hours, and that the total loss of candle-power due to blackening was about 22 per cent.

These measurements enable us to account for rather more than one-third of the loss of candle-power suffered by the lamp. We are not, with our present knowledge, in position to speak so definitely concerning the other two-thirds, but the increase in the

resistance in the carbon indicates another source of diminution. That gradual failure of the vacuum which the use of the spark-coil would unquestionably have enabled the observers to detect, may well be answerable for the rest. Now, the temperature of an incandescent lamp filament at five watts per candle is very nearly the same as that of the carbon in the light-giving flames produced by the combustion of oils and gas, and it appears that the attempt to pass this temperature introduces difficulties of such a nature as to lead to the serious question whether we have not reached a definite limit, beyond which incandescent carbon ceases to be permanent.

At that limit the efficiency of the lamp is very small indeed, 95 per cent. or more of the radiant energy emitted being of wave lengths too long to afford light.

As to the arc light, no more encouraging report can be made. On the contrary, it is perfectly well established that the quality of the light, instead of increasing, has fallen off, in the course of the development of the lamp from the clock-work regulators of Dubosc and Foucault, with their slender carbons, to the commercial lamps of to-day.

The researches of Nakano,[3] Marks[4] and others, show that the efficiency of the arc is a definite function of the current density at the terminals of the carbons, increasing nearly in inverse ratio to the cross section of the pencil. When the maximum current capacity of the latter has been reached, the efficiency is in the neighborhood of 10 per cent., a value which is not likely to be greatly exceeded by any of the methods in vogue at the present day.

As Mr. Edward Weston[5] says in his discussion of Nakano's paper on the efficiency of the arc lamp: "The small amount of luminous energy, compared to the total energy employed, is a sad thing always."

In the vast accumulation of experience which the past years have witnessed, nothing has come to general knowledge which looks to the raising of the barrier which blocks our progress. It seems only too probable that the limiting temperature at which carbon can be used for the production of light has been reached, and with it the maximum efficiency of artificial illumination.

The phenomena observed whenever we attempt to raise carbon above what may be termed its normal temperature of incandescence are significant, and they all point in one direction. We have just seen that when we raise the voltage of an incandescent lamp, we gain splendor of performance at the cost of permanence and stability. I might remind you, in this connection, that when the heat of gas flames is increased by forced draft, they become non-luminous; that the magnificent illuminating power of the arc lamp is not due to the intensely hot electric arc itself, filled, though it be, with carbon in process of transfer from the positive to the negative pencil, but to the cooler carbon terminals. Such are the facts with which we have to deal when we consider the problem of increasing the efficiency of illumination

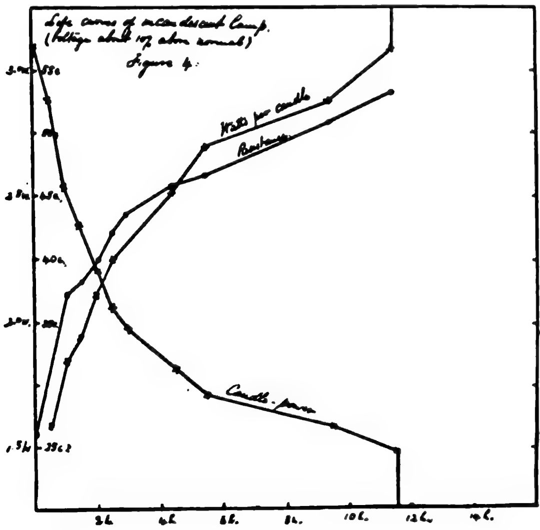

FIG. 4.

by carbon, whether by direct combustion, by incandescence in vacuo or by the use of the electric arc. In the face of the many unexpected things that have been accomplished through the agency of electricity, he would be rash who asserted that the possibilities of carbon had been exhausted. In view of the achievements of the time one is not permitted to declare the case hopeless; nevertheless, the outlook is not an encouraging one.

If, in what I have said thus far, I have drawn what seems to be a gloomy picture, it is not because I fail to recognize the importance of the electric light of to-day as a factor in our civilization. Its superiority over other methods of artificial illumination is so well understood that it need not be enlarged upon here. Of its advantages we hear on every hand; of its limitations we hear less; and yet a knowledge of the latter is quite as important to those who are interested in its further development. The waste of 90 or 95 per cent. of non-luminous energy in the production of light is a matter to which we are apt to give little thought, and when the economic importance of the fact has been forced upon us by the study of the recent investigations which have been made to establish it, we find consolation in the thought that, after all,

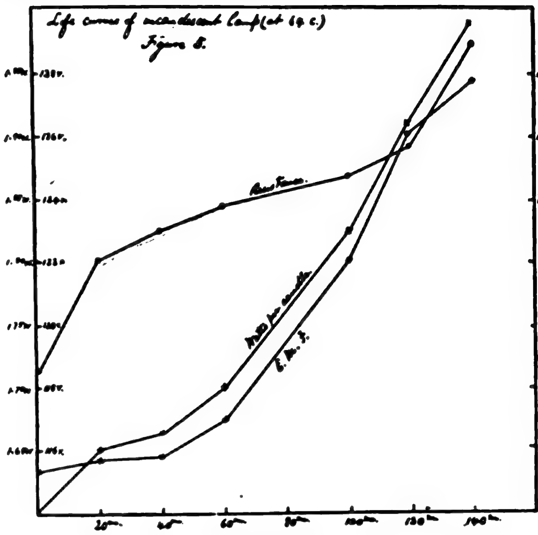

FIG. 5.

those percentages are somewhat larger than the corresponding values for candles, oil and gas.

As time goes on, however, the question of the efficiency of illuminants will increase in practical importance. No one of us, I take it, is of the opinion that the world will always be content with the present extravagant methods of obtaining light. Progress in these matters is chiefly a question of the careful and exhaustive study of the properties of the substances with which the inventor and engineer have to deal. As in the past, so to-day and in the future, researches in the laboratory must prepare the way for operations in the workshop and manufactory. I have thought it not without interest, therefore, to discuss the behavior of incandescent carbon under conditions, some of which are not "commercial," and to attempt to point out the significance of that behavior. Now, if you will permit me, I will turn toward the future and consider the properties of some other sources of light, with the view of inquiring whether they may not have a part to play in the artificial lighting of days to come.

What is to be the light of the future? From the standpoint of the engineer I will frankly say that I cannot answer that question, but abandoning the directly practical point of view, there is something to be said. I need offer no apology here for presenting facts, the application of which is at best remote, and the present importance of which is therefore rather scientific than utilitarian; nor need I remind you that all the so-called "forces of nature" which have been yoked and impressed into the service of man were the object of scientific curiosity and the subject of scientific investigation long before the idea of a practical application was entertained.

The number of elements and of compounds capable of sustaining a high temperature without dissociation or change of state is very large. Carbon is the only one of these, the capabilities of which as a source of light, can be said to have been fully tested; and yet all the others, when heated to a proper point, emit light-giving radiation. Take for example the metallic oxides. We heat the oxide of calcium in our magic lanterns and it gives us a light of great intensity and but little inferior to the arc light in whiteness. The exceeding clumsiness of our method of rendering it incandescent, however, has prevented its adoption excepting for certain special purposes. We burn magnesium in fire-works and for photographic flash lights, and occasionally we indulge in the luxury of igniting a bit of the ribbon and admiring, for an instant, the intense brilliancy of its flame. Now, magnesium is one of the most abundant elements on the face of our planet. It is a rather costly metal at present, being quoted at 50 cents an ounce in this country and at about half that price on the continent of Europe. Even under the limited demand for it which exists at present, it has fallen to about one-tenth of its price of a few years

ago, and I feel sure that it lies within the power of the electrician to greatly further reduce the cost of production. Among artificial illuminants, magnesium has in one respect no equal. W. H. Pickering, who studied its spectrum in 1880, found it to approach sunlight in quality even more closely than the electric arc light does.[6]

The precise character of the magnesium light is shown in Fig. 7. The abscissæ of the curves are wave lengths, and ordinates indicate the brightness of each portion of the spectrum of the magnesium flame in terms of that of the corresponding regions in the spectrum of gas light. The accompanying curves for the arc light and the lime light, introduced for convenience of comparison, are from measurements by Mr. W. S. Franklin and myself. These curves all refer to lights of the same candle-power. It will be seen that the magnesium flame is about 10 times brighter in the violet than a gas flame of the same power, and but little more

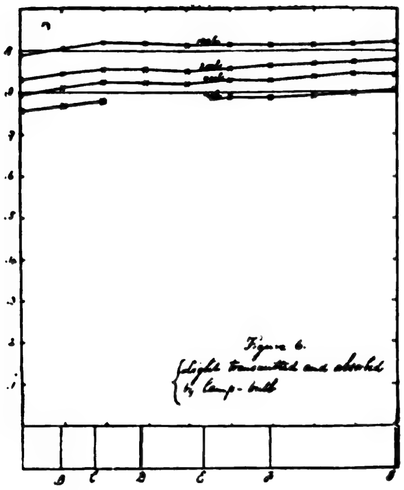

FIG. 6.

than half as strong in the red. It will be seen, also, that it surpasses the electric arc everywhere beyond the yellow, save in a very limited region of the extreme violet. In order to appreciate fully the significance of these curves, one must have had occasion to compare the various lights to which they refer, placing them side by side and noting the effects. You are all aware that the magnesium light is very white and very powerful, but unless you have happened to see it in direct competition with our ordinary illuminants, you will be but dimly conscious of the difference between them.

I have here a simple magnesium lamp of European manufacture. By means of a simple arrangement of clockwork, it feeds a thin magnesium ribbon at a rate just sufficient to maintain a flame of between 40 and 50 candle-power. Turn your attention for a moment to the screen just behind us. It gives you the impression of a nearly uniform white surface, which is well lighted by the incandescent lamps with which this hall is so abundantly supplied. Its whiteness now, however, is a very different thing from that which it will take on under the rays of the magnesium light. I light the little clockwork lamp, placing it so that it illuminates a portion of the screen. That part which is shaded from the lamp is just as well lighted as it was before, and its tint is in no way changed; but no one would be likely to describe it as a white surface under the present circumstances. It has sunken by comparison into a rather weak chocolate brown. Let us turn the lamp so that you can see the burning magnesium, and place beside it, to emphasize the contrast, this lighthed candle. How dull and sickly the candle flame appears, and yet, though old-fashioned and rather out of date among our modern glow lamps, the candle does not suffer greatly, so far as quality of light goes, by comparison with them.

I have been much interested in studying this source of light, and I will venture to give you some of the results which I have obtained. This lamp consumes 168 milligrammes of magnesium per minute. It is difficult to determine its candle-power by ordinary methods, because of the enormous difference between the color of its light and that of gas light. By means of measurements made with the horizontal slit photometer, an instrument the use of which entirely obviates this difficulty, I found the light to average slightly more than 40 candle-power. Assuming 40 candles to be the correct value, we have 4.2 milligrammes of magnesium consumed per minute per candle. Now to maintain one candle-power of gas light one minute with an average quality of illuminating gas, 137 milligrammes of gas must be consumed. With gas at $1.00 per 1,000 cubic feet and magnesium at $10.00 per kilogramme, a price which is in excess of the present European rate, the magnesium light would cost, candle for candle, about 6.72 times as much as gas. With magnesium at $1.49 per kilogramme, or about 67 cents a pound, the cost of the two illuminants would be the same. Looking at the matter from a slightly different point of view, we may say that since 4.2 milligrammes of magnesium will give as much light as 137 milligrammes of gas, their relative productiveness as illuminants is as 33.1 to 1. The true relation between their value is, however, expressed by a larger ratio than that since, candle-power for candle-power, the real worth of a source of light increases with its temperature. The total luminosity of the arc light, for instance, may be considered fully 25 per cent. greater than that of gas. Two candle-power of sun light is the equivalent of three candles of gas light. The luminosity of the magnesium light lies between these two values.

The proper way to compare sources of illumination is to determine their net and gross efficiencies; by which I mean, respectively, the ratio of total radiation to light-giving radiation, and the ratio of the total amount of heat set free in the process of producing a candle-power of light, to the heat energy represented by the light itself. Now the heat equivalent of a candle-power of gas or of the light of an incandescent lamp at five watts per candle, is about 3.6 gramme-calories per minute. The total heat of combustion set free in generating a candle-power of gas light has been variously estimated at amounts ranging from 971 gramme-calories per minute (Preece) to 4,100 gramme-calories (Thomsen). Calculations based upon the theoretical heats of combination of illuminating gases, give values nearer the latter than the former amount.

The amount of heat set free when a gramme of magnesium is converted into the oxide is very much less than that resulting from the combustion of a gramme of coal gas, and the light obtained is, as we have just seen, more than 32 times as great. The gross efficiency of the magnesium light must, therefore, be many times higher than that of gas light. To be exact, we find, if we adopt the value given by Thomsen[7] for the heat of combination of magnesium (6077), that the magnesium flame of one candle-power should generate only 25.52 gramme-calories per minute. Taking the very low estimate of 1,000 gramme-calories per minute for gas, *we find the gross efficiency of the magnesium flame to be about 40 times that of gas light.*

The simplest method of determining the net efficiency of a source of light is that recently applied by Mr. Merritt to the study of the incandescent lamp.[8] I have measured the efficiency of the magnesium flame by Merritt's method, which consists in receiving the radiation upon the face of a thermopile. A glass cell containing a solution of alum is placed between the flame and the pile. This cuts off almost all those rays which do not produce

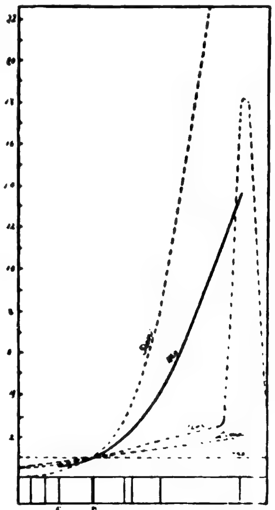

FIG. 7.

light and permits about 75 per cent. of the luminous waves to pass. After observing on a suitable galvanometer the deflection produced by the light giving radiation, the cell is removed and the deflection noted again. The ratio of these two readings, properly corrected, gives the net efficiency of the source of light. In the case of the magnesium flame, at least 15 per cent. of the total radiation was found to belong to the visible spectrum. Let us consider the matter from another point of view. When we disperse the rays from any source of light by passing them through a prism or reflecting them from a diffraction grating, we find that we have to do with a great many rays which are of a wave

6. W. H. Pickering: *Proceedings* of the American Academy of Arts and Sciences, vol. xv., p. 240.

7. J. Thomsen: *Journal für Praktische Chemie*, N. F., 16, p. 97.
8. Ernest Merritt: *American Journal of Science*, vol. xxxvii, p. 167.

length too great to affect the eye. These constitute what is called the heat spectrum, and they are accompanied by a few rays which are of the wave lengths capable of optical action. By means of the thermopile or the bolometer, it is possible to explore the whole spectrum, and to determine the intensity of the radiation of each wave length which the source emits. From these values the curve of distribution of heat in the spectrum may be plotted. The curve consists of two parts: That which gives the energy of the light-giving rays, and that which shows the amount of radiation outside of the visible spectrum. The ratio of the areas enclosed by these two portions of the curve is the net efficiency of the source of light. Such curves for the flames of candles, oil and gas show that less than two per cent. of the total radiation is luminous. In the case of the incandescent lamp the amount rarely exceeds five per cent. The arc lamp contains about ten per cent. of useful rays. The magnesium light, therefore, according to the data which I have just presented, possesses a much higher net efficiency than any of the other sources of artificial illumination. To what does it owe its superiority?

We have seen that, weight for weight, magnesium affords more than 30 times the light obtained from gas, with the development of much less heat. The quality of the light is such that merely from the standpoint of illuminating power, to say nothing of the additional æsthetic value of a light which approaches sunlight in whiteness, each unit of it must be regarded as the equivalent of rather more than 1.25 units of light.

The character of the light corresponds to a temperature much above that of the electric arc, but the flame does not seem to be very hot. I have not as yet succeeded in obtaining a satisfactory measurement of the flame temperature, but a preliminary test, made at my request, gave approximately 1,400°C. This value, which is presented subject to correction, enables us to classify the magnesium flame, at least placing it among those the temperature of which is far below the melting point of platinum. Its temperature, probably, does not differ widely from that of the luminous gas flame.[9]

The large candle-power of the magnesium flame is due to its peculiar structure. A gas flame consists of a column of heated gases, the particles of which are rising rapidly from the jet of the burner. These carry off with them, by convection, 80 per cent. or more, of the heat of combustion. The flame owes its luminosity entirely to the fact that near the base of the column a few particles of carbon, as yet unoxidized, are heated to incandescence. The total radiating surface of these particles is very insignificant, compared with the apparent superficial area of the flame; it is, indeed, not very different in extent from the radiating surface of the filament of an ordinary incandescent lamp of the same candle-power. The constitution of the magnesium flame is very different. The product of combustion is the oxide of magnesium, a white, amorphous solid of considerable density; it is, indeed, fully twice as heavy as the metal itself. The oxide remains, for the most part, in the place where it was first formed.

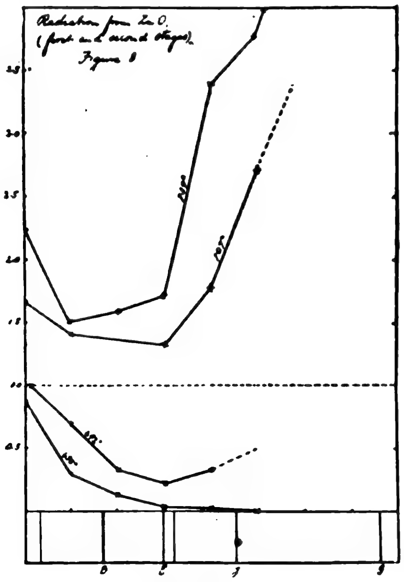

FIG. 8.

It becomes intensely incandescent, and having large radiating surface, it affords a large amount of light. Under such conditions, convection plays a minor part, and that which is the chief source of loss in the production of light by direct combustion of gaseous fuels is avoided. The gross efficiency is, therefore, very large.

The question of the *character* of the radiation from the magnesium flame offers greater difficulties. It is certain that neither platinum nor carbon at any temperature to which they can be subjected in practice, will give anything approximating to the quality of the magnesium light. I am convinced that we have to do here wilh a very different law of radiation from that which governs ordinary cases of incandescence. Taking carbon to represent the normal state of affairs, we may say that the radiation of magnesium oxides is out of all proportion to the temperature of incandescence; also that the precentage of those shorter wave lengths, which furnish green, blue and violet light, is abnormally large. That the radiation of the magnesium flame

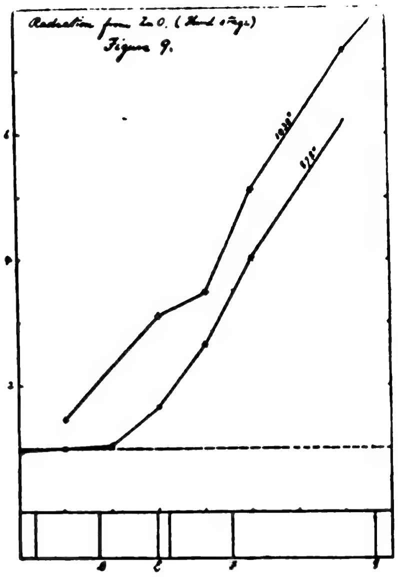

FIG. 9.

comes in part under the head of what Prof. E. Wiedemann has termed "Luminescence," I have little doubt. This word covers all these interesting phenomena known as phosphorescence, fluorescence, etc.

Luminescence is supposed to be due to a different class of molecular vibrations from those which cause ordinary incandescence. One of the characteristics of this class of vibrations is that it tends to produce selective radiation; that is to say, radiation in which a single wave length, or set of wave lengths, predominates. Another characteristic of luminescence is, that it is frequently, perhaps always, the result of previous treatment to which the glowing body has been subjected. This previous process may have been nothing more than the shining of the sun's rays upon the luminescent surface, as in those cases of phosphorescence concerning which Becquerel has taught us so much.[10] It may have been in the course of some chemical reaction or process of crystallization that the body received its preparation. In such cases the power lies latent until it is disengaged by the action of some external force.

The immediate exciting cause may be mechanical, electrical or thermal. In the last case, which most directly concerns us here, a certain rise of temperature is necessary to start the body into luminescence. When this critical temperature is below the red heat the phosphorescent glow attracts attention, and investigation follows. When, however, the temperature of luminescence is high, the effect, however marked it may be, is masked by the ordinary incandescence to be expected at that temperature, and it is overlooked. Luminescence by heat is perforce transient. It is due to the expenditure of energy which has been stored by previous action. If we wish to see the effect repeated we must restore to the material the potential energy which it has lost.

I am not in position to state positively that the glow of magnesium oxide is due to luminescent vibrations, but I am of the opinion that such will be found to be the case. Other metallic oxides also show peculiarities of radiation which find their explanation most readily under that theory. While studying the distribution of energy in the visible spectrum of the lime-light, three years ago, Mr. Franklin and I found that a freshly ignited cylinder, under the oxy-hydrogen flame, glowed with a brilliancy equal to that of the magnesium light itself.[11] This state of affairs lasted but a moment, however, and no amount of heating would bring out an old cylinder again into its initial splendor. It was plain that we were taking advantage of vibratory power stored in the lime at some stage in its preparation. These vibrations, dis-

9. Rossetti (*Beiblætter zu den Annalen der Physik*, 2 p. 333) gives us the temperature of the gas flame, 1840°: of the positive carbon of the arc, at the hottest point, 3,900°: of the negative carbon, 2,450°.

10. Becquerel; *Annales de Chimie et de Physique* (3), 55; p.

11. See the *American Journal of Science*; vol. xxxviii, p. 100.

engaged by the blowpipe, gave out in a very short time, after which the performance of the lime degenerated rapidly to the level which corresponds to ordinary radiation at the temperature in question.

You are all acquainted with the beautiful greenish-yellow light which the oxide of zinc emits under the flame of the blowpipe. It is entirely different from the light of the incandescent charcoal on which it lies, although the two cannot differ widely in temperature. The zinc oxide is luminescent, the carbon is simply incandescent, in the usual sense of the word. This is a case which lends itself readily to study, since the temperature at which the abnormal glow appears, is a comparatively moderate one. Last summer I took the matter up, with the efficient coöperation of Mr. B. W. Snow, Instructor in Physics in Cornell University. We made a systematic comparison of the radiation from zinc oxide and from platinum, at temperatures between the red heat and 1000°C., measuring temperatures and studying spectra by methods which I cannot dwell upon here. Since the results which we obtained are of a character to illustrate the points which seem to me most significant, in this question of the radiation of the metallic oxides, I will indicate them graphically.

Zinc oxide is a rather brilliant white pigment. Its radiating power, therefore, according to the theory of exchanges, should be very small. At temperatures below 700°C. we found it to be very much lower than that from platinum throughout the spectrum, and the light from the oxide to be of a duller red. Fig. 8 shows the results of the comparison. In this and the subsequent curves, platinum is taken as the standard. The curves show how the oxide of zinc compares with platinum in strength of radiation. The law according to which the visible radiation of platinum rises from zero at the extreme red heat, as the temperature rises, varies with the wave length. It had to be especially determined for the purposes of our investigation in each region of the spectrum to which our measurements were extended.

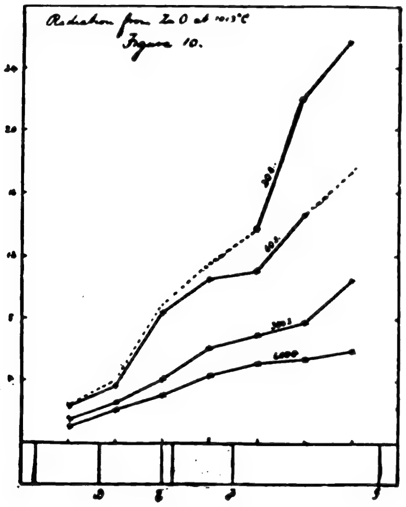

FIG. 10.

At about 700° a sudden change occurs in the character of the light from the oxide. It becomes brighter than the platinum of the same temperature, the increase showing itself principally at the ends of the spectrum. In Fig. 8 (707° and 739°) we have curves which represent this second phase. The emanations are selective to a marked degree, the yellow being relatively very weak. Measurements of fresh films of the oxide at still higher temperatures revealed the further development of the abnormal radiation of this substance. Fig. 9, which gives curves for 878° and 1,084°, shows the transition into a third, and, apparently, a final stage. The red end of the spectrum loses its prominence, and the curve seems to be developing into a straight line, the trend of which is such as to indicate that zinc oxide, as we pass from the longer to the shorter wave lengths of its spectrum, increases in superiority over platinum at the same temperature.

It soon became evident, from the character of our results, that the radiation at temperatures above about 800° were of a very evanescent sort, falling off in intensity and changing in quality from the first instant in which the oxide was heated. To follow these rapid changes proved a trying task. By taking a great many fresh films of the oxide and watching the time changes of one portion of the spectrum after another, however, we were able to obtain data from which the curves in Fig. 10 were drawn. These show the intensity of radiation and its character, relative again to that of platinum, after the oxide had been maintained 1,013° for a period of 30 seconds, of 60 seconds, of 300 seconds, and of 600 seconds. At the end of the 10 minutes the changes, although not entirely completed, were very slow.

The evidence of the existence of luminescence afforded by these measurements seems to us to be nearly conclusive. Extension of the investigation to other of the metallic oxides, and to wider ranges of temperature, would, doubtless, lead to results more striking.

The application of all this to the problem of the light of the future is as follows. The fundamental question is that of efficiency. High efficiency at low temperature means selected radiation, which appears to be a characteristic of luminescence and not of ordinary incandescence. The study of the radiation of the metallic oxides above the red heat reveals the existence of properties which lead us to regard them as being luminescent "by heat." It is from such bodies that radiation of high efficiency is to be looked for. We have in magnesium oxide a member of this particular class, and we have seen that when it is heated in the process of formation it gives us a light the efficiency of which is unapproached by that of other artificial illuminants.

The problem is easily stated. (1) We need a body which is rendered vividly luminescent by heat.—The metallic oxides would seem to offer us many such. (2) The material is to be brought to the temperature at which its luminescence is most marked.—Does it not seem probable that the best method, as in the case of carbon, will not be that of direct combustion, but of heating through the agency of the electric current? (3) The material must be restored from time to time.—Whether rejuvenation is to be secured through electrical, chemical, actinic or mechanical means remains to be determined.

Luminescence "by heat" offers, however, only a partial solution of the problem of the highest efficiency. However great the efficiency of the luminescent itself, it is accompanied by incandescence of the ordinary kind. The ultimate solution is to be sought for along other lines. Incandescence is too expensive a means of exciting luminescence. There are many other ways in which it may be generated; friction, chemical action, the impact of light waves, electrical excitation, certain vital processes, are known to result in the production of light. The physics of these phenomena is, for the most part, undeveloped. I know of but two attempts to determine the efficiency of this "light without heat," as it has sometimes been called. The intensity is, as a rule, very small, and the heat has doubtless been regarded as quite below the range of even our most sensitive apparatus. One of these two cases is of especial interest to the electrician. It is that of the spark discharge in vacuo. Prof. S. P. Langley and Mr. F. W. Very, in a recent remarkable paper, entitled, "The Cheapest Form of Light," speak of the heat generated in the Geissler tube as so minute as to seem to defy direct investigation. It has, however, been successfully measured by Dr. Staub, of the University of Zurich, by means of one of the most delicate instruments for the measurement of heat—the Bunsen ice calorimeter.[12]

In Staub's experiments the vacuum tube was smoked with lampblack and inserted in the ice calorimeter. The ice melted in a given time afforded a measure of the total heat generated by the electric discharge through the tube. A repetition of the determination with the unsmoked tube, under which conditions the light-giving rays could escape, gave the energy of the non-luminous radiation. The efficiency was found to be 3.268 per cent. The extremely small candle-power of the light derived from the electric discharge in vacuo, may seem to preclude all questions of its utilization in practical illumination. The result is one, however, which should not be lost sight of. It suggests a field of investigation which may prove unexpectedly fruitful.

The Geissler tube effect was not the source to which Langley and Very applied the term "the cheapest form of light." The subject of their research was the light of a Cuban fire-fly. Their work cannot fail to excite the highest admiration of every one who is able to appreciate the difficulties of such an investigation. The exploration of the heat spectrum of so insignificant a source of light is a task which very few physicists, would, I think, have considered practicable, but it has been carried through by these investigators to complete success.

When we study the curve of distribution of energy in the spectrum of the fire-fly thus obtained, and compare it with the corresponding curves for gas light, the arc light and sun light, we find the expression, "the cheapest form of light," which is applied to the light of the fire-fly by Langley and Very, to be fully justified. All the energy of its spectrum is massed within the narrow limits of the visible spectrum, and what is more, by far the greatest part of it is in the form of rays which are especially important for the purposes of radiation, the particular rays which give us yellow and green light. The non-luminous radiation which accompanies the light of the fire-fly seems to be so insignificant that it was with difficulty that it could be estimated, even with the almost inconceivably delicate apparatus used by Langley and Very. They give the efficiency as about 400 times as great as that of a gas flame. It cannot fall appreciably below 100 per cent.

In what I have said this evening, I fear that I have fallen far short of what might have been expected of a lecturer on the artificial light of the future. I have endeavored to show that the

12. G. Staub: Inaugural Dissertation, Zurich, 1890. (See the *Beiblaetter zu den Annalen der Physik*, 14; p. 538.)

efficiency of our present methods is too low to meet the demands of the future for economical illumination, and that whether we ever succeed in approaching the perfect economy of nature's light-making processes, as exemplified in the fire-fly, or not, there are many sources of light which promise high efficiency. If I have succeeded in indicating, even vaguely, some of the conditions of the problem of the utilization of these, and in pointing out some of the lines of investigation which are to be followed in the development of new methods of lighting, my mission has been fulfilled.

CORNELL UNIVERSITY, Nov., 1890.

COLUMBUS MEETING OF THE OHIO STATE TRAMWAY ASSOCIATION.

THE ninth annual meeting of the Ohio State Tramway Association was held in Columbus on Nov. 19, and was called to order by Hon. J. N. Stewart, vice president, of Ashtabula, O. A large number of delegates and trade representatives were present.

Afternoon session called to order by President Stewart at 2:30 o'clock.

MR. C. K. HARDING, president of the Harding Electric Railway Co., of Atlantic, Ia., described his system as follows:—"It was to avoid some of the overhead and other difficulties that I devised the conduit system to which I desire to call your attention. Heretofore the word "conduit" has been almost inseparably connected with some slotted arrangement, and failure and failure, for it should be understood to preserve insulation you must exclude water, and to do that the conduit must be entirely closed, without slot or other opening through which the current is taken. In order to accomplish this result I employ a tubular iron casing, in the top of which is a channel or flanged portion in which is insulated and supported the section of working conductor. These sections may be from four to six feet long and extend an eighth of an inch or more above the surface and are normally insulated from each other; the casing and the main conductor which extends through the lower tubular part is entirely surrounded and embedded in insulating material. In the end of each section of the casing or conduit, there is an enlargement of the lower tube which forms a junction box in which is located a small electro-magnetic contact making device, which when operated connects its conductor section with the main or supply conductor. One end of the winding on the magnets of these contact devices is connected through a simple switch to the adjacent working conductor section, and the other end directly to the conductor section on the other side by means of this arrangement and a second brush on the car. I employ a very small portion of the current to automatically operate the contact device and bring the exposed sections of working conductor separately and successively into connection with the main insulated supply conductor when these sections are immediately under the car and protected by it.

In other words, I get the current to the car through the series of insulated exposed sections which are fed from the main conductor as the car passes along and are at all other times completely insulated from the wire carrying the current. By the employment of a derived circuit in multiple arc with the motor circuit I am enabled to use a very small portion of the main current for the operation of the contact devices, and to make the magnets of small size and wind them with iron wire, thus making the construction of the contact making devices a comparatively simple matter and enabling them to be placed in a small closed cavity in the end of the sections where they will be readily accessible and are adapted to be interchangeable.

It will be readily seen that the short exposed sections of working conductor will have very high insulation and prevent all but the most inappreciable amount of leakage when it is taken into consideration that under no possible combination of circumstances can any sections except those immediately under the car be brought into or maintained in connection with the supplying current. The placing of the wire underground will remove the possibility of any trouble from lightning; and the position of the wire and the fact that the return current passes through the track rails and the conduit casing near to and parallel with the supply current precludes the possibility of inductive interference with telephones.

MR. CURTISS, of the Short Electric Railway Co., said:—"I do not know that I can say anything to the convention regarding the Short system with which you are not already perfectly familiar. The largest contract ever let in this country by disinterested parties was given by a syndicate of Philadelphia gentlemen for equipping the street railway system of Rochester, New York, to our company. That, as you probably know as well as I, was given after a very thorough and careful investigation by experts who came to our factory, went through the works, visited our system working in different places and made their report. On the basis of that report the purchase was made for Rochester.

Now, that which has heretofore been, I believe, the curse of electrical railroading in its practical operation, was the one item of repair. I see gentlemen here who know very well how much this has amounted to. In one town, I am told by gentlemen connected with the road that the repairs last year amounted to as high as $1,100 per car. When I went into the Short Company they had a road running in Muskegon, Mich., equipped with our system. That road had been running for six months, commencing with five cars and at the end of the six months having nine cars in operation, and the total repairs on that road have not exceeded $100 on all the electrical equipment. You can appreciate the advancements which we have made. We believe we have got now to very near the perfect theoretical point, and we invite cordially your investigation in that direction.

There is one point that I have had called to my attention since I arrived, only proving that a man must go away from home to get information regarding one's own business. I heard remarks in the convention on consolidations. If there has been any consolidation of the Short Electric Railway or any other railway, it has occurred since I left home this morning at seven o'clock. I do not of course know where the rumors may have started, but there is no foundation for them in fact.

MR. C. A. BENTON, of Detroit, Michigan, as representing the Rae system, then said:—I represent the only "single motor" system that I believe is in successful operation. The peculiar feature of our motor over that of other systems is, that it is geared to both axles, a construction which permits the use of large wearing parts, slow speed of armature shaft, and therefore reduced friction and long life. It secures perfect insulation between the motor and the truck, eliminating all electrical strain and making burn-outs from this cause impossible. By the way, reference has been made to the economy of electrical street railroading, and as to the extent of repairs required. A statement has been made in your presence by Mr. Curtiss which was intended to impress you with the belief that his system reduced the expense of repairs to the minimum. To borrow a slang expression, "I will go him one better." Mr. Curtiss says that six cars running for six months at Muskegon, Michigan, required repairs to the extent of $100. We have twenty-one cars running at Saginaw, Michigan, which have been run for eleven months and the repairs on the entire equipment have not reached the sum of $50. A man who went there to do the winding in case of a break had nothing to do, and they finally bought him a uniform and have been using him as an extra conductor on the line. This is absolutely true, and if you don't believe it you can go there and see him. Some people think we are a little bit new in this business, but we are not. Several years ago, in fact six years ago, about 1883 I think, Mr. Rae first built an electric motor, and during the time which has elapsed between that time and this he has been busily engaged in perfecting it. We have during the last two months closed certainly some important, even if they were in the minds of some, small contracts. Mr. Curtiss, how many cars were in your Rochester contract?

MR. CURTISS—1,000.

MR. BENTON—Well, ours is not over a quarter of that. (Laughter.) However, we think we can run four times as well and four times as long as the other system, so we will even it up. (Renewed laughter.) The Detroit Electrical Works are in this position. They are sound financially, their guarantees are good, they are prepared to send a truck motor to any responsible street car line having any system and put a car upon it and leave it for them to use. Now, gentlemen, if you care to, I can show you a model that I have in my room at the Neil House, or, what is better still, we will have one running here tomorrow on the Glenwood and Green Lawn road. It would have been here to-day but for the same kind of a mishap as that which occurred to Mr. Brickwood with his carette; the steam railroad failed to keep its promise in getting it delivered here by the time agreed upon.

MR. CLEGG—What is the weight of your motor as compared with others?

MR. BENTON—It varies very little from the Sprague, or the Short. I think it is a little lighter than the Thomson-Houston.

MR. CLEGG—It struck me that it was much lighter.

MR. BENTON—There is but very little difference. The weight, of course, would vary some from this reason, that we weigh them on the trucks and sometimes we have heavy wheels on the truck and sometimes not so heavy, and for this reason the weight varies a little.

MR. F. B. BROWNELL, of the Brownell Car Company, St. Louis. Missouri, then spoke as follows:—The leading subject now among street railroad people, I think, is the subject of electricity as a motive power; but it has always appeared to me that the proper amount of thought has not been given to the mechanical construction and operation of the car. Electricity itself is a matter that I know very little about, in fact almost nothing, but the transmitting of the electric current to the car axles through mechanical appliances, is in my judgment far from being perfect. We have a very large electric road in St. Louis now that has been in operation only a very short time. In conversation with the superintendent a few days ago he told me that the defects in the electric trucks were very many, and that it seemed to him (and to me also) that the people jumped at the construction of the electric truck without giving the matter proper consideration.

In most of the electric trucks that I know of, the motors are located very close to the ground. The movement is very rapid, and the tendency to draw in foreign substances from the street is very great, and I do not believe that we are going to get an economical car until some change is made in the location of your motor. The thought has occurred to me that the present electric car in general use is only the ordinary street car, but made more elaborate and finer and larger and better finished inside, but the motors are located on the trucks underneath this car. Now if there is anything the matter with your car to prevent its running, it will be most likely in the trucks.

The result is that you have to run this expensive car into your car shed, and throw up the trap doors, and the mechanics get in there with their soiled clothes and greasy hands, and throw tools and traps up on the cushions in their effort to repair the track, and the car is very apt to be injured and costs not a little money to put it back. It would seem to me that the better mode would be the use of cars in trains, a motor car with a passenger coach as elaborate as you see fit to use and the more elaborate the better it would be for the car builder (laughter); the motor car to be made small and strong and plain so that the liability to injury by the handling of tools and parts of the mechanism of the car would not be much, and then to have that motor car used entirely for that purpose.

I have thought also that the motors instead of being horizontal and close to the ground, should be located vertically and so arranged that every part could be easily got at for repairs or removals or renewals, or whatever might be necessary to do with them and the whole system of construction changed to something that is practical and desirable, which the present mode I do not think is.

Then again there is another subject, which I think should be considered, in connection with the operation of these electric and cable roads, and that is the fearful liability to accident. You can scarcely pick up a daily paper but what you will find an account of some one killed on an electric or cable road in some part of the country. I find that nearly all the electric cars, and nearly all the cable cars, excepting of course those built by ourselves (laughter), have got a fender or so-called life-preserver constructed somewhat after the principle of a locomotive pilot. Apparently the parties who first built an electric or cable car, saw the necessity of something, and without stopping to think, they concluded that the locomotive pilot was just what they needed. Now, the locomotive pilot is not designed to preserve the life of anything that may be on the track. The engineer of a locomotive, if he sees a man or an animal on the track, will try to stop his locomotive; if he sees that he cannot do it, then he will open the throttle and give the engine all the steam she will take and he will knock that object sky high and get it out of the road, and thus prevent the derailment of his locomotive and the possible wrecking of his train and great loss of life. Nearly all the switch engines around the yard, where the movement is slow and the liability to obstruction is great, are provided with a sort of platform on which a man could jump and be carried along with the locomotive until it can be stopped thus preserving life as well as preventing the derailment of the engine. This is a subject I think it is well for the railroad people to consider; the subject of fenders. There are cases on record where lives have been saved by this style of a fender, and there are many cases where lives have been lost on account of having other styles of fenders.

These two subjects I think are worthy of some thought, and I think if the railroad companies and the motor people will work in harmony on that line, and especially so far as the location of the motors are concerned, they will find that many of the troubles of the street car companies and the electric companies will be removed, and that a large portion of the money that is now used to pay the cost of repairs, can be utilized as dividends, which I am sure will suit you all very much better (applause).

MR. JOHNSON, representing the Northern Car Company, of Minneapolis, stated that the Northern Car Company was comparatively a new company and comparatively unknown to the general street railroad men of the country. The company is only about four months old. They have at Minneapolis, the largest street car factory in the United States, if not in the world. Pullman has about 32,000 feet of working surface, and the Northern Car Company has about 75,000 feet of working floor surface. They have a system of electric lights by which they can work at night when it is necessary; and in fact every contrivance in the way of machinery, tools, buildings, dry-houses, etc., by which they can make practically perfect cars.

MR. FERDENING, president of the Dayton Street Railroad Co., said: We are operating a street car line in Dayton, which we think is doing very well. We still stick to the mule and the horse. We have had under consideration and have investigated somewhat, the different modes of motive power, and had thought very seriously at one time of adopting electricity as a motive power. Yet we were not fully convinced that electricity had yet arrived at that stage when we felt justified in adopting it, and preferred to let others do a little more experimenting. I have been told by a gentleman, who had a great deal of experience in electricity as a motive power, that they are very well satisfied with it, and I have no doubt but that it is the coming motor for street car service.

MR. W. J. COOKE, vice-president of the McGuire Manufacturing Company, said: I have been very much interested in what I have heard this afternoon. I am here to learn. I commenced building trucks several years ago when cables first came in. When electricity was first introduced we had a truck which we thought was peculiarly adapted for electricity. I found out from the electric people that they had designed that the standard should be thirty horse-power. I figured from thirty horse-power up to a truck, following the suggestions of the electrical people largely. When I had completed my truck, my electrical friends said I was wild, simply crazy; that I had 1,500 pounds more than I should have. I insisted that my figures were right. The result was I did not sell any trucks for six months; they thought I had too much strain. In the last year, however, I could not make trucks enough; I am making them heavier than ever and I do not think that they are heavy enough. They have been figuring the standard on the other side from the basis of a two-horse team and came down, while I started from 30 horse-power and went up. We are not quite reconciled yet.

I am glad to hear what my friend, Mr. Brownell, has to say in regard to it. It coincides with my opinion exactly. I believe that the present mode of connecting the motor to the truck is not right. You are now getting the motor down in the mud and the dust and the dirt, and this of course creates friction in the gearing and that cuts and consequently requires repair. I do not know how the remedy is to be accomplished, but I have an idea that we will have to get up on top with our motive power. We are at the mercy of the electrical and street railway people. We want to build whatever they want. We have gotten out what we believe is pretty near the requirements of to-day, but we are ready to adopt any new device or to make any modification that the demands of the street railway people may require. We have very recently, at a very great expense, gotten up a frame made of pressed steel, the entire frame consisting of only four pieces. Noise has been a disagreeable feature to some extent in the electric motor; some motors are very noisy and some trucks are very noisy. We have gone to work and made a truck of very few pieces, less than half the number I believe used in any other truck constructed to-day. We had it on exhibition at Buffalo; a pair of trucks under a double truck car. We believe that that solved the question to a great extent of the expense as to wear and tear of truck and motor. Until very recently we have not had the matter taken up. We have now under contract 200 pair of these trucks for three different lines in Pittsburgh—double trucks; also for Sioux City; Salt Lake City; Los Angeles; Oakland, Cal., and several other places, where they have recently adopted the double truck car, 24 to 30 feet in length. We are of the opinion that that is the coming car for street car service. One long car instead of a trailer. It makes less expense on the cars, the friction will be practically nothing and it makes a saving of flange wear on the tire. The wheel base is 4 feet, 6 inches on the long car; just enough to let the motor in. The electrical people wanted us to make it longer, but we are trying to get the wheel base as near the gauge of the car as possible and we have adopted a standard of 4 foot 6, and arrange it so that we can get all of the present motors in that wheel base. Mr. Rice, of Pittsburgh, who has used these short wheel based trucks for a good many years under his cable cars, is of the opinion that it is the most economical style of truck to use, both as to rail wear, wheel wear and motor wear. On our double truck, we extend the spring base 3 feet wider, thus doing away practically with oscillation of the car, which is also very hard on the rail, wheel and motor.

SECRETAY HANNA—Can you tell the gentlemen present anything about the new electric heater we were talking of this morning?

MR. COOKE—Yes, just a little. The gentleman representing the heater expected to be here. He is an old school friend of mine, and that accounts for the interest I take in it. It was invented in Minneapolis. I have one in my house in the laundry. I take off the burner in the house and connect the wire and my laundress irons all day by means of this heater. The iron only gets so hot; it can't get any hotter, and it holds that heat a long while.

He has arranged a heater for a street car. I am sorry he is not here to explain it himself. It is merely a ribbon that runs along under the edge of the seat, I think about 6 or 8 inches wide and possibly a half or three-quarters of an inch thick, and with the current from the trolley, he heats the car perfectly to any degree of heat that is necessary. There is a button attachment at the motorman's command, so that he can give the car quarter heat, half heat, three-quarters heat or full heat, just as the demands of the weather may require. I merely make this statement in behalf of my friend, who has just recently taken hold of it, and who expected to be here to-day and give you an exhibition of it.

MR. C. B. FAIRCHILD, associate editor of the *Street Railway Journal*, N. Y., then addressed the convention by invitation as follows: I am very glad to have the opportunity of looking in your faces and of making myself known to you at this time. The hour is too late for me to enter into much of a discussion. I would like, however, in the first place, to disabuse your minds of

one thing. The street railway men seem to think that the technical press are very much on a par with the reporters of the daily papers, and sometimes you have been afraid to let us into your meetings and afraid to talk before us as you would among yourselves. Now, we wish very much that you would regard the technical press—at least the paper that I represent—not as a newspaper watching you, to pick flaws in your work and criticise you unfavorably, but as one working in the interests of the street railway companies. We would like to have it understood that we are, to all intents and purposes, a street railway company, interested in the same line of work you are interested in, and that your interests are our interests; that we come to your meetings, not merely as repor ers, but to learn and to publish that which will be of benefit to you and others. You need not be afraid of our publishing anything that is said in confidence among yourselves.

Now, just one word in regard to conventions, and particularly in regard to the Ohio convention. Those of you who have read the *Street Railway Journal* recently, have probably noticed that we are urging that more attention be given to these conventions. It seems to us that you do not fully appreciate what a power you might be in this State if all the street railway people felt obligated to be present at these meetings, or at least to contribute papers and take hold of this matter in earnest and place this Association on a solid foundation.

We hear a great deal of complaint, Mr. President, about unfair legislation, both from State and municipal authorities. I believe that if there is any more unjust or unfavorable legislation by which the street railway men suffer, that they will have themselves to blame for it. I believe that with proper organization among the street railway men of the State, they could influence legislation; or at least stop unfavorable legislation against street railway companies. It seems to me that the most important object to be attained by this convention is to secure some remedy in this direction. Take up this subject as was suggested in the papers read at the national convention last year and this year by Mr. Scribner, and pursue it in the line which he has indicated. Present the matter to your legislature and keep it before them until you have secured your rights. Remember the old adage "They have rights who dare maintain them." If you dare maintain your rights, undoubtedly you can get them.

You are a power and by united effort you can get justice at the hands of your law makers and make them to understand that you are determined to make your business more pleasant, more prosperous and more satisfactory to yourselves and to the community (applause). There is a great deal which might be said upon this subject. I simply speak by way of suggestion. I do not think anyone should go away from here feeling that this Convention has been a failure by any means, but let each member see to it that the interest which has been manifested this afternoon be continued and increased among all the street railway men of your State, so that at next year's Convention you will have a large meeting and one that will exercise a salutary influence over law makers. I hope your meetings will continue to be profitable and pleasant.

PRESIDENT STEWART then asked if Mr. Beggs or Mr. Lewis, representing the Edison General Electric Company, were present and desired to be heard.

MR. WILLIAM HAND responded to the call of the Chair and stated that to his regret neither Mr. Beggs nor Mr. Lewis was present, but that as he was working in the interest of the Edison General Electric Company, as an electrical expert, he would like to state that he had just completed the installation of the Glenwood and Green Lawn Street railway, of Columbus, Ohio, extending about four miles west from High street, with five cars, with the Edison system. The road has been in operation over two months and the repairs on the cars during that time had not amounted to one dollar; there had not been an armature taken out of any of the cars.

PRESIDENT STEWART then, after putting the motion to the Convention, declared the Association adjourned to meet at Akron, Ohio, on the second Wednesday of November, 1891.

CONVENTION NOTES.

ONE of the most entertaining features of the convention was the special *Street Railway Gazette* car from Chicago, carrying the following party of gentlemen to Columbus: Payson K. Andrews, of the Brill Car Co.; W. J. Cooke, of the McGuire Mfg. Co.; A. H. Englund, of the Electric Merchandise Co.; D. F. Morris, of the Milliken Pole Co.; C. K. Harding, of Atlantic, Ia.; R. M. Johnson, of the Northern Car Co.; John N. Reynolds, of the *National Car and Locomotive Builder* "*Supplement*;" D. B. Dean, of *the Electrical Review*; J. B. O'Hara, of *The Western Electrician*; W. Forman Collins, of THE ELECTRICAL ENGINEER. The car arrangements were in the hands of E. V. Cavell, editor of the *Street Railway Gazette*, and S. L. K. Munro, manager of the same journal, the former of whom made a most perfect "quartermaster" on the occasion and both gentlemen laid themselves out to entertain and amuse the party and their efforts were highly successful.

On Wednesday, at 7:30 p. m., a banquet was held at the Columbus Club, in its handsome dining room through the kindness of General Manager Sheldon. It was attended by the street railway men, supply men and representatives of the technical press. A most enjoyable evening was spent and some first rate speeches were made. The model of the Milliken pole decorated with smilax adorned the table as the centre piece. An elegant repast was served accompanied by exquisite vintages, and all expressed themselves delighted with their sojourn in Columbus.

THE DETROIT ELECTRICAL WORKS were ably represented by Mr. Charles A. Benton, who exhibited a very beautiful working model of their motor and truck equipment. The motor is of the well known "single motor" Rae pattern as fully described in a recent issue of THE ELECTRICAL ENGINEER, and possesses some very important and novel features. The truck was made by the Sheffield Velocipede Car Co., of Three Rivers, Mich., and is provided with rigid bearings on the non-oscillating principle, constructed of two frames with springs equally distributed throughout their entire length. It is made of wrought iron and amongst the merits claimed for it are adaptability to all systems of electric propulsion, superior design and workmanship, easy riding, non-oscillation, and freedom from tilting motion, strength, durability and economy. Mr. H. F. Probert, M. E., the inventor, was in attendance explaining its many advantages.

THE ELECTRIC MERCHANDISE COMPANY, of Chicago, were represented by the versatile secretary and treasurer of the company, Mr. A. H. Englund, who showed some very handsome rawhide pinions, various forms of pullover brackets and other devices for electric street railway work, and the Englund centre curve insulator, a new and meritorious device which is meeting with universal success and sells at sight. The street railway men were deeply interested in the various specialties shown, the advantages of which Mr. Englund showed up in a most picturesque and entertaining manner.

ILLINOIS ELECTRIC MATERIAL CO.—The interests of the Illinois Electric Material Co., of Chicago, were looked after by Mr. Ernest L. Clark, their well and favorably known secretary. Mr. Clark had numerous samples of their street railway devices, among others, the Murray overhead switch which attracted great attention and many words of the highest commendation from all who saw it, including some who are using it on their roads. A new pole ratchet also elicited considerable satisfactory comment. Mr. Clark was also busy as regards poles and was walking around with a large contract for wooden poles.

MR. D. FORSYTHE MORRIS, the Chicago manager of the Milliken Pole Co., brought with him a very handsome model of these poles, which are meeting with such success for ornamental street railway construction in cities. More than 7,000 of these poles have been sold in the past four months, and Mr. Morris states that he is ready to supply any quantity.

MR. CHAS. K. HARDING, president of the Harding Electric Railway Company, of Atlantic, Iowa, was busily engaged during the convention in explaining his new underground conduit system which possesses some highly ingenious and advantageous features. Mr. Harding will have his system in practical operation in the very near future, when undoubtedly some important developments of this method of operating electric street railways may be expected.

MR. J. S. COLLINS, of the Meaker Manufacturing Company, had on exhibition in the hotel one of his new fare registers operated mechanically, which is being largely used on street railways.

ELECTRICITY IN THE NAVY.

Commodore G. Dewey, Chief of the Bureau of Equipment, in his annual report to the Secretary of the Navy, says: "The lighting of ships of war by electricity, which was inaugurated by this Government, has now become so essential that no war ship is considered complete which is not so lighted. During the year substantial progress has been made in the development and advancement of the system, which is being employed in the new ships, and progress abroad has been critically noted. Electric lighting plants have been installed on board seven vessels, and the work of installation is actively progressing upon four others. Special attention has been given during the year to the subject of means of interior communication on shipboard, and a telephone system is soon to be added experimentally to other devices in use on board one of the new cruisers. Night signalling by electricity has also been, and is still actively, under consideration, and it is believed that a system will have been devised in the near future which will meet the increasing necessity of the service in this respect. The great importance of an adequate method of communication at night between ships of a squadron or fleet makes necessary the utmost care in the consideration of the subject."

INVENTORS' RECORD.

DIGEST OF ELECTRICAL PATENTS ISSUED NOV. 18, 1890.

Alarms and Signals:—

Push-button, H. Von Kohler, 440,818. Filed May 31, 1890.

Designed for simplicity, cheapness and proper protection of contact points.

Conductors, Conduits and Insulators:—

Electric Conduit, W. J. Brewer, 440,822. Filed July 15, 1890.

Specially applicable to electric railways. Conduit with conductor of two plates or rods insulated from each other and surrounded by a flexible rubber tube, contact pieces, held in position by springs, passing through the rubber tube and projecting upwards into slot to be actuated by trolley. Adapted, also, to single conductor in conduit. Rail having a bracket piece, forming, with the rail, a conduit, in combination with the above.

Underground Wire System, E. Verstraete, 441,043. Filed Feb. 21, 1890.

An underground conduit system for electric wires. An iron structure with supporting bars upon each side to hold insulating strips for wires or cables and with a passageway and a railroad track in the centre of the conduit for the transit of reels. Conduit slotted at the top which is flush with the road-bed throughout its length, for convenience in inserting and removing wires; slot normally closed by sectional caps.

Dynamos and Motors:—

Electric Collecting Device or Brush, H. P. Brown, 440,691. Filed June 6, 1890.

Brush or contact-maker composed of graphite and clay mixed together.

Electric Motor, C. E. Dressler, 440,699. Filed April 10, 1890.

A cylindrical field magnet with pole pieces at each end and wound on the outside with insulated wire, a rotary armature core in the axis of field magnet within an interposed coil of insulated wire and with pole-pieces at each end. The coils being so wound that the field magnet and armature when energized have opposite polarity at each of their ends, whereby the combined energy of the whole of both field magnet and armature is exerted attractively at the ends to rotate the armature.

Electric Motor, H. B. Pullman, 440,776. Filed Aug. 16, 1890.

To secure equipoise of the armature on its centres, and to obtain a nicety of adjustment of the pole-sectors of the field magnet.
Armature has a counter-balance, adjustable on the web of the armature to and from the axis of the armature.

Yoke and Brush-Holder, F. B. Rae, 440,817. Filed Aug. 9, 1890.

Designed to be easily applied, adjusted or removed.
Yoke provided with collar made in two complementary portions, each portion somewhat smaller than half the circumference of the bearing therefor, and connecting devices between the two parts.

Electric Motor, L. Bock, Jr., 440,821. Filed Aug. 20, 1889.

A reciprocating motor; a series of solenoids with a converter for reducing high tension alternating currents, the coils or solenoids of the motor being in the secondary circuit of the converter.

Dynamo Electric Machine and Motor, F. V. Anderson and J. O. Girdlestone, 440,908. Filed May 13, 1890.

Design and construction for reduction of weight and for simplicity and economy of manufacture; also, to reduce the magnetic resistance of the air-spaces around the armature to a minimum.

Generator for Pulsating Currents, C. J. Van Depoele, 440,977. Filed April 17, 1890.

First claim as follows:
1. A system of generating rising and falling currents, comprising a revolving armature of the continuous-current type rotating in a suitable field of force, and means for causing the magnetism of said field of force to rise and fall, reacting upon the armature to produce defined rising and falling currents therein.

Lamps and Appurtenances:—

Electric Arc Lamp, E. Thomson and E. W. Rice, Jr., 440,662. Filed Jan. 3, 1884.

A high resistance derived circuit magnet, a feed-controlling mechanism to suspend or normally hold the carbon-carrier in proper relation to the opposite carbon, a support for the feed-controlling mechanism actuated by the derived circuit magnet in one direction to feed and in the opposite direction by a suitable retractor, a starting circuit, a circuit-controller with which a part moving with the feed-controlling lever engages when the lever is in an extreme retracted position, and a spring for throwing the circuit-controller out of range of the movements of the lever when the lamp mechanism has been brought to operative position.

Electric Arc Lamp, E. Thomson and E. W. Rice Jr., 440,663. Filed Jan. 3, 1884.

A high-resistance derived circuit magnet whose armature lever supports the carbon-electrodes and is actuated in opposite directions by the magnet and by a retractor, a starting coil on the core of the derived circuit magnet, a circuit controller for throwing the starting core out of action, and a magnet in the carbon branch and in a circuit independent of the derived circuit magnet for operating the circuit controller.

Apparatus for Flashing Filaments, H. Lemp, 440,759. Filed Feb. 1, 1889.

Flashing current automatically cut out of circuit when the filament reaches the desired resistance. Second claim follows: An apparatus for flashing filaments for incandescent lamps, embodying a circuit containing the filaments immersed in a hydrocarbon bath, a low variable-resistance circuit normally shunting the same, a second circuit of higher resistance containing an electro-magnet in a constantly-closed circuit, and contact devices in said low variable-resistance circuit controlled by the operation of the aforesaid magnet, substantially as described.

Incandescent Electric-Lamp Socket, J. W. Collier, 441,059. Filed Nov. 16, 1889.

Made from a plastic non-conducting material having solidly molded and embedded in it the holder contacts and the separate wires for connections, and having a solid hermetically closed base.

Measurement:

Electric Meter, S. Z. DeFerranti, 440,627. Filed Oct. 9, 1888.

First claim as follows: 1. In an electric meter, the combination of a rotating armature, registering mechanism driven thereby, a coil carrying the current to be measured and within the field of which the armature rotates, and a compensating coil of higher resistance also acting to produce rotation of the armature.

Metallurgical:

Process of Magnetically Concentrating Ore, G. Conkling, 441,060. Filed Oct. 12, 1889.

First coarsely crushing ore to a size required by its natural granular formation without reducing any considerable portion of the ore to dust, then concentrating the ore by the action of magnets, then screening the concentrate to separate the richer ore, then re-crushing the ore refused by the screen, and finally concentrating the re-crushed ore by the action of the magnets.

Metal Working:

Electric Welding Apparatus, H. Lemp, 440,641. Filed June 13, 1890.

Invention consists, essentially, in constructing the apparatus with a plurality of secondaries in the transformer arranged parallel to one another. The several secondaries may have the same or different iron cores or magnetic circuits. Adapted to apply current to the same or to different parts of the work in multiple arc.

Electric Welding Transformer, H. Lemp, 440,640. Filed Apr. 16, 1890.

Welding apparatus designed particularly for classes of work in which the areas of material to be heated at once are extended or subdivided, and which are liable to heat unevenly. Secures uniform heating at different parts of the work by supplying them from different sources of energy and regulates the different sources independently. Specially adapted to the formation of the two separate welds or joints simultaneously in parallel. Second claim follows: 2. The combination, with a compound transformer comprising two or more secondaries and corresponding primaries therefor applied at different parts of a common iron core and having magnetic bridges from one side to the other of the core, of means for regulating the current-flow in the primaries independently of one another.

Method of Electric Welding, E. Thomson, 440,664. Filed May 15, 1888.

Invention consists essentially in the repeated application alternately of a heating current and pressure to the pieces to be welded.

Miscellaneous:

Electric Switch, E. T. Barberie and J. DesBrisay, 440,614. Filed Apr. 8, 1890.

A fixed electrode, pair of movable electrode arms adapted to grip the fixed electrode, the latter operated by hand through a pair of links.

Lightning Arrester, E. W. Rice, Jr., 440,654. Filed Aug. 15, 1889.

First claim follows: 1. The combination, with the electric apparatus to be protected, of a lightning-arrester in a branch to earth of low self-induction, and a self-inductive coil interposed between the said apparatus and the point of connection of the lightning-arrester.

Electric Cut-Out, G. H. Alton and E. W. Rice, Jr., 440,685. Filed Nov. 21, 1889.

A fuse wire mounted between terminals upon an insulating plate, safety fuse clips or electrodes made as spring jaws, which project from their supports so that their openings will be in position to permit a fuse to be slipped in edgewise between them by a movement of such fuse bodily toward the support upon which the jaws are mounted.

Electric Switch, C. A. Pfluger, 440,720. Filed Jan. 15, 1890.

Two vertically tilting levers insulated from each other, one being longer than the other, the longer being pivoted midway of its length and the shorter in the same horizontal plane but at its extremity, the pivotal points connected to the main circuit binding posts and the same levers adapted to engage contact points connected with local circuit.

Cross-Over Block, F. Bathurst, 440,753. Filed March 31, 1890.

Device for securing and insulating wires at points of crossing.

Electric Switch, C. H. Herrick, 440,845. Filed Aug. 19, 1890.

Rotary "snap" switch.

Ceiling Block, D. A. Tompkins, 440,944. Filed Dec. 31, 1889.

Cut-out for incandescent lamp circuits.

Thermal Protector, H. V. Hayes, 441,066. Filed July 17, 1890.

For the protection of the instruments in telephonic and telegraphic circuits not only from the very strong currents of light and power circuits, but from lesser "sneak currents" that are dangerous to delicate instruments but not strong enough to operate ordinary protectors now in use.
A movable switching arm or contact piece, tending to connect an alternative circuit with main line, held in disconnection by a stop of easily fusible metal and a heat concentrating device, as a coil of high-resistance wire, for directing the heat developed by a current of undue strength in the main line upon the fusible stop.

Railways and Appliances:

Trolley-Arc for Electric Railways. E. Thomson, 440,665. Filed Mar. 5, 1889.

Trolley-arm designed particularly for use where the distance between the vehicle and the wire or conductor varies materially; and to cause the roller or contact to be carried directly over the centre of the length of a car when the wire is overhead. A double-jointed arm, the upper section of which, carrying the trolley, inclines in an opposite direction to the lower section which is attached to the car, the two arms resembling a toggle joint; a spring attached to the lower end of the upper section of the arm tending to expand the angle between the two arms, and thus to keep the trolley in contact with a conducting wire at various heights and over the longitudinal centre of the car.

Signaling Apparatus for Electric Railways, F. F. Loomis, 440,881. Filed Mar. 15, 1890.

An auxiliary wire is connected with the feed wire and provided with signaling apparatus arranged to be actuated by the current from the feed wire when a ground connection is made with the auxiliary wire.

Trolley for Electric Railways, C. A. Lieb, 440,814. Filed June 13, 1890.

Trolley-pole vertically supported by springs placed on opposite sides of the base and in the same horizontal plane therewith; connections between the springs and the pole by which it is elastically supported against pressure in all directions.

Electric Railway-car Motor, L. F. Baker, 440,686. Filed July 1, 1889.

Sleeving the motor or a part attached to it to the car axle at one end and supporting the motor at the opposite end by an elastically sustained bar, which is engaged by a projection upon the motor or motor frame, the projection sliding freely on the supporting bar.

Electric Railway Car, W. S. Belding, 440,699. Filed Apr. 21, 1890.

Continuous rotation of armature of motor, whether car be in motion or stationary. Means for engaging and disengaging armature shaft with wheels or axles of car. Propulsion of car in either direction without changing the direction of rotation of motor.

Electric Motor and Generator, C. E. Dressler, 440,700. Filed May 12, 1890.

A machine to act simultaneously as both motor and generator. A field magnet or magnets, a rotary electro-magnet armature and an induction coil helically wound at right angles to the armature's axis and inductively excited by the armature.

Electric Motor Mechanism, S. E. Mower, 440,717. Filed May 8, 1890.

Relates particularly to speed reducing mechanism. Motor has its armature secured to a sleeve loosely mounted on the axle; speed-reducing mechanism consists of a disc fast on the sleeve, a gear fast on the axle, a gear loose on the armature sleeve, a shaft having bearings in the said disc and provided with a pinion in mesh with the gear on the axle and with a gear in mesh with the gear loose on the armature sleeve, a friction disc or drum loose on the armature sleeve and secured to the gear on the armature sleeve, a friction strap to engage the friction disc, and means to engage the strap with the disc.

Electric Motor Mechanism, S. E. Mower, 440,718. Filed May 10, 1890.

Similar in purpose to above. Motor has its armature secured to a sleeve loosely mounted on axle; speed-reducing device consists of a gear fast on the armature sleeve, a disc mounted on the axle and having a recess in its periphery, a shaft carried by the disc, a movable box for said shaft, and a gear fast on the axle, and a friction strap encircling the movable box and disc.

Underground Conductor, E. Verstraete, 440,780. Filed Feb. 21, 1890.

For electric railways. A conductor grooved on its under side for the passage of a trolley, and insulated and protected at top and sides.

Trolley or Plow for Electric Railways, E. Verstraete, 440,781. Filed Feb. 21, 1890.

Weight-actuated levers, contact-bearings carried by the levers, and a frame to which the levers are pivoted.

Overhead Conductor for Electric Railways, R. D. Cushing, 440,789. Filed Dec. 16, 1889.

A bifurcated insulating guard or covering enclosing the upper surface of the conductor and partially overhanging it, leaving its under surface exposed to the trolley wheel.

Electric Railway, S. Trott, 440,905. Filed April 26, 1890.

Protection of contact brushes, in conduit system, from falling moisture. Contact-brush of carrier or plow protected by the expansion of insulating material in the form of a hood immediately above the brush. Applied to either single or double conductor system.

Railway Signal, J. W. Riggs, 440,925. Filed Aug. 31, 1890.

For the automatic signaling of trains approaching a bridge endangered or of which the structure has been carried away by a flood. Signal operated by a float when water has risen sufficiently to endanger the bridge.

Railway-Signaling Device, J. W. Riggs, 440,926. Filed Sep. 12, 1889.

To prevent accidents to trains approaching burning bridges. Thermostatic signal.

Railway Signaling System, J. W. Riggs, 440,927. Filed Sep. 12, 1889.

To prevent derailment of trains when a switch is out of place.
1st claim is as follows:
1. The combination, with a track the rails of which are arranged in sections and to break joints and are insulated from each other at their meeting ends, an insulated conductor, and a switch in said track, of a switch-stand, mechanism contained therein for actuating the switch, a contact-piece and connections from such piece to the track and insulated conductor substantially as and for the purpose specified.

System of Electric Transmission of Power, C. J. VanDepoele, 440,976. Filed May 10, 1886.

Utilizes the momentum of electric railway cars, as when running down a grade, for the generation of current, through an organization which permits the motor to be used as a generator and to add the current produced by it to the main current of the line.

Train-Signal for Railroads, W. D. Sheldon, 441,030. Filed June 15, 1889.

Signaling the approach of a train in advance; signaling in advance and in the rear of a train the position of the train; and lighting the road-bed in advance of a moving train.
Along the track of a railroad a circuit of two conductors with a dynamo and a series of electric lamps, one terminal of each lamp connected with one of the conductors and the other terminal connected through a circuit-closing device with the other conductor, operative connections between the circuit-closers by which when one circuit-closer is actuated by the passage of a train its lamp is lighted and the other circuit is opened and its lamp extinguished.

Train Signal, W. D. Sheldon, 441,031. Filed Sept. 20, 1889.

A switch-operating mechanism operated by a passing train and by which an electric current is applied to an electric motor actuating a day-signal some distance in advance of a train.

Railroad-Gate, W. D. Sheldon, 441,032. Filed Sept. 20, 1889.

A railroad crossing gate operated by an electro-motor the connections of which are automatically operated by the passage of a train.

Train Signal for Railroads, W. D. Sheldon, 441,033. Filed May 15, 1890.

Lighting the tracks of railroads in advance and in the rear of moving trains. Lamps normally short-circuited; passing train breaks the short circuit and lights the lamps on a given section of the road.

Lighting Railroads, W. D. Sheldon, 441,034. Filed May 15, 1890.

Lighting a railroad and signaling the approach of a train. Sections of electric conductors suspended over the track and connected with electric lamps; a source of electric energy carried on the train and connected by wipers or trolleys with the overhead conductors.

Electric Railway Signal, W. H. Waddell, 441,044. Filed Oct. 21, 1889.

Two separate and distinct conductors located on opposite sides of the track in overlapping sections insulated from each other, a signal alarm and signal source of electrical energy on the locomotive.

Telegraphs:—

Telegraphy, P. B. Delany, 440,766. Filed May 11, 1886.

Relates to synchronous-multiplex telegraphy.
Places the correction-receiving segment sufficiently behind the position of the correction-sending segment as to compensate for the retardation upon a line of considerable length.

Synchronous Telegraphy, P. B. Delany, 440,767. Filed July 30, 1886.

First claim is as follows:—
1. The combination of the several segments for correction, messages, and grounding, said segments being arranged in a circle independently insulated and provided with independent binding posts or contacts, so that they may be independently connected, as desired.

Multiplex Telegraphy, P. B. Delany, 440,768. Filed July 30, 1886.

Running the circuit-completer at the transmitting end ahead of that at the receiving end by a distance proportional to the time of retardation of the line; sending impulses into the line in succession in one direction only and irrespective of whether each preceding impulse has reached the receiving station, and receiving such impulses as arrive at the distant end of the line in their proper succession, according to the time of the line.

Telephones and Apparatus:—

Calling Device for Clock Telephone-Lines, J. A. McManman, 440,898. Filed March 21, 1890.

Central-station apparatus for use upon telephone lines containing a number of subscribers.
A clock mechanism carrying a revolving dial plate, a series of contact plates beneath said dial plate, each wired to a spring jack and the spring jacks wired together to a generator; a circuit-making and breaking device connected with the dial plate.

SOCIETY AND CLUB NOTES.

ELECTRICAL DEPARTMENT—BROOKLYN INSTITUTE.

On Friday evening last, Nov. 21st, Dr. S. S. Wheeler, the expert of the New York Board of Electrical Control, delivered a most able and interesting lecture on "Some Applications of Electricity." It was fully illustrated by a large variety of experimental demonstrations.

TELEGRAPHERS' MUTUAL BENEFIT ASSOCIATION.

The annual meeting of the Telegraphers' Mutual Benefit Association was held at 195 Broadway, N. Y. City, November 19th, Vice-president Young in the chair. President Merrihew's report referred particularly to the membership question. He said among other things: "Your especial attention seems to be necessary in the direction of increasing the membership—such increase should be steady and gradual. The agents, who are all busy men, should neither be expected nor depended upon to do all the work. It is a matter of personal interest with the members, each of whom should be an active solicitor, interesting his fellow workers, especially the young men, in the history and objects of the Association; and it should be the pleasure—as it is the duty—of every member to aid in increasing the membership. The fraternal co-operative spirit exhibited by the founders of this Association, 23 years ago, should be renewed by the young men of the present, and the Association pushed ahead with vigorous enthusiasm. In the early days, as many of you will remember, the obstacles were many and the difficulties great—to-day, the young men have a perfect organization, a good system, a liberal contract and a reserve fund of almost $100,000—a right good start." Secretary Fleming's report showed that out of a total of 155 applications received, 149 were accepted, 4 rejected and 2 withdrawn; 28 deaths were reported during the year and 99 members lapsed, leaving a net increase in membership for the year of 22 members. The treasurer's report showed receipts from assessments and initiation fees, $41,559.75; from interest, $5,508.57. The sum of $13,000 has been added to the reserve fund, bringing the total par value of that fund to $99,508.92. The following named gentlemen were elected as officers for the ensuing year: President, James Merrihew; vice-president, W. H. Young; secretary, Thomas E. Fleming; treasurer, G. W. E. Atkins; executive committee, James Merrihew, New York, G. W. E. Atkins, New York, W. B. Gill, Philadelphia, Thomas E. Fleming, New York, W. H. Jackson, New York, S. C. Mason, Chicago, W. H. Young, Washington, Joseph L. Edwards, New York, C. W. Hammond, St. Louis; auditing committee, S. S. Garwood (chairman), Philadelphia, W. J. Dealy, New York, M. J. O'Leary, New York.

After the meeting, the Magnetic Club gave its opening dinner, at Martinelli's, over 100 gentlemen attending. Dr. Norvin Green was one of the guests of the evening. A most enjoyable time was spent.

The Short Electric Railway Co. report the following contracts for the two weeks of November (to the 15th) for electrical equipment: The Schuylkill Electric Railway Co., Pottsville, Pa.; the Watervliet & Turnpike Railway Co., Albany, N. Y.; the Texarkana Street Railway Co., Texarkana, Ark.; the Lindell Ave. Railway Co., St. Louis, Mo.; the Syracuse & Onondaga Railway Co., Syracuse, N. Y.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"STANDARD" INSTRUMENTS FOR ELECTRICAL TESTING.

WE illustrate, in the accompanying engraving, a new form of ammeter and voltmeter designed especially for central station, laboratory and battery work, manufactured by the Electrical Supply Manufacturing Company, of Manchester, N. H., and sold

"STANDARD" DIRECT-READING AMMETER.

exclusively by the Standard Electric Supply Company, of Boston. These instruments are manufactured on the highest plane as to accuracy and finish, and are carefully calibrated before leaving the factory. It has been the aim of the manufacturers to supply a thoroughly reliable instrument at a reasonable figure, and from the success which these instruments have attained, they have achieved the desired result. The readings, both on the voltmeters and ammeters are direct, and the needle is very dead-beat in its action. The instruments are made for various purposes, and they can be procured either for fractional readings of a volt or ampere, such as for battery work, or for very high readings, such as for street railway work. The goods have now been on the market long enough to prove their value, and the Standard Electric Supply Company are already doing a brisk business in supplying the demand.

HEAVY SHIPMENTS OF WESTINGHOUSE APPARATUS.

In order to fill the rapid demand for the various manufactures of the Westinghouse Electric and Manufacturing Company that firm has lately been obliged to augment considerably its facilities for shipping the goods from the works to the different railroad stations in the city of Pittsburgh. A number of wagons are constantly engaged in hauling motors and machinery, but as the company's own teams were not sufficient some of the local express companies had to be asked to aid in the work.

During the month of November, the shipments of the company will amount to 40 alternating current incandescent dynamos, aggregating a total capacity of 30,000 16 c. p. lamps. To this must be added 1200 alternate current meters. The demand for this measuring device of the Westinghouse Electric and Manufacturing Co. has for months been particularly pressing, and the detail department at the Garrison alley shops, where these meters are manufactured, is taxed to its utmost capacity. The same remark holds good in regard to the Westinghouse converters, the high efficiency of which has created a very favorable impression for them wherever they have been used. The company is in almost daily receipt of letters and communications from places where the converters have been introduced, which speak in exceedingly flattering terms of their operation. It is stated, that during the entire time in which the company has manufactured and sold these converters, not one has ever been returned for fault of construction or inefficiency. This, it must be acknowledged, shows a remarkable record for a piece of workmanship, of which thousands are now in use throughout the world.

It is now a little more than two months since the electric street railway in Lansing, Mich., the first road operated by the Westinghouse electric street railway system, started. Since then the Westinghouse company has completed the equipment for twelve roads, which to-day are running to the utmost satisfaction of the purchasers and manufacturers. A few days ago, the managers of the Lansing road, in a letter to the Westinghouse company, stated, that although they had a number of difficulties to surmount in the construction of the road, they were glad to say that everything had been overcome, and that they felt positive the Lansing electric railway is to-day the best equipped street railroad in this country. It must not be forgotten, however, that while speaking of difficulties, that term in no wise referred to the motor equipment of the road. In fact, as far as the Westinghouse motor is concerned, it is said that the apparatus runs as smoothly and noiselessly to-day as it did on the first day it ran along Main street, Lansing.

The Westinghouse Electric and Manufacturing Company has now increased its capacity of the motor department to an extent which enables the firm to manufacture and ship 100 motors per month. The company has at the present time 50 new roads under process of construction, and as the facilities and the working capacity of the motor department are constantly increased, it is expected, that within a very short time, the supply will be equal to the current demand.

STAR ELECTRIX CEILING CUT-OUT.

We illustrate herewith, in Figs. 1 and 2, a new ceiling cut-out, which embodies several improvements. It is manufactured by the Star Electrix Company, of Philadelphia, who are pushing its sale together with their other specialties. This is claimed to be the neatest and best designed ceiling cut-out which has appeared up to date. The main wires are screwed just 2¼ inches apart, which avoids bending the wires at the cut-out. It is easily wired,

FIGS. 1 AND 2.—THE STAR ELECTRIX CEILING CUT-OUT.

yet there are no bungling screws or castings on the side to disfigure it. The cut-out is said to be meeting with great favor already, with supply men and contractors.

RECONSTRUCTION WORK AT LANCASTER, PA.

The reconstruction work by Pattison Bros., of 135 Broadway, N. Y., at Lancaster, Pa., has given such entire satisfaction that the same parties have put the Williamsport station into this firm's hands for a similar treatment. Mr. Chas. E. Pattison is in charge of the work and has already begun the alterations and repairs.

EUREKA TEMPERED COPPER CO.

The Eureka Tempered Copper Co., of North East, Pa., has issued a neat little pamphlet giving full details as to the qualities of its product and including a large number of excellent testimonials. This admirable material is now beginning to be appreciated as it deserves by electrical and engineering concerns, for commutators, trolley wheels, bearings, boxes, &c.

EXHIBIT BY W. H. GORDON & CO. AT THE AMERICAN INSTITUTE FAIR.

Messrs. W. H. Gordon & Co., 115 Broadway, have on exhibition at the fair the Automatic Clock Co.'s specialties. The principal attraction in the exhibit is the automatic cut-out clock for cutting out incandescent lights in stores or show windows at any given time. These clocks have a switch attachment and are particularly desirable for stores wishing to advertise by having their show windows brilliantly lighted during the evening. The other clocks in the exhibit have attachments for ringing bells in servants' rooms, opening dampers on furnaces, in short, doing automatically many of the things about a residence night and morning, even to feeding horses. A clock was shipped to Atlanta, Ga., recently, to unlock a door at a set hour. The Gardner Governor Co. uses one to open two heavy iron doors on their japanning ovens; a Lockport firm, to turn off a gas meter; while the Syracuse Gas Co. uses one to turn off their large Lungren burner.

Orders for the clock and cut-out for incandescent lights are coming in quite freely, and merchants are beginning to recognize their utility, convenience and economy.

THE HUNT ENGINEERING CO.

A great many enterprises have recently sprung up with the sole purpose of electrical construction and taking charge of the commercial application of electricity, and it is a practice of the large manufacturing concerns to let their construction out on contract, and where reliable parties have been entrusted with this task, it has proved the best policy.

The Hunt Engineering Co., 177 Montague street, Brooklyn, to judge from their success in the past, are destined to take a prominent part in the construction field. They will manufacture the goods which they need with the exception of dynamos, lamps and instruments. At present they have under construction the Norwich Opera House, Norwich, Ct., an isolated 650-light plant; Republican Press Association, Concord, N. H., an isolated 300-light plant; the Cordis Mills, Milbury, Mass., an isolated 300-light plant; central station at Dover, N. J., 1,000 lights; central station at Jamaica, L. I., 2,000 lights, both of the latter being alternating National system. They are the patentees of an improved key socket, the patent for which was granted within a few days. The men controlling this company are well posted on all the details of the business. G. W. Hunt is president, A. E. Rich, general manager, Alex Henderson, superintendent of construction, DeWitt N. Cole, civil and consulting engineer.

THE AMERICAN TANNING CO.

The American Tanning Co., P. O. Box 1189, New York City, has just been organized and is now introducing the Worms and Balé process of electric tanning described on page 587 of this issue. The method is a very simple one and the economy of the process is such that electric tanning may be looked forward to as a well established improvement in the art. Besides the enormous saving in time, an increase of over 10 per cent. in weight, as compared with the old method is obtained in the finished product. Information can also be obtained from Mr. A. Cuyas, 80 Wall St., the agent of the inventors.

JEROME KIDDER MFG. CO.

DR. H. S. HERRICK, of Hamilton, Nev., in a recent letter to the above company, of this city, says: "This is the sixth battery I have had of your manufacturing during the last twenty years. There have been any amount of electrical machines in this Western country during the last decade. In my practice I am willing to acknowledge that Kidder's battery far excels any other for durability and medicinal purposes."

J. G. WHITE & CO.

A new firm of electrical engineers and contractors has come into existence under the above style, with offices at 50 Broadway, this city. The principal, Mr. J. G. White, was general manager of the well known Western Engineering Co., of Kearney, Neb., which made so many excellent installations in the West and was finally consolidated with other enterprises of the kind. The firm will make a specialty of electric railway work, and will contract to furnish complete equipments or separate details, without restriction as to system or manufacturer. They are ready to make bids on any plant, to be built or enlarged, and invite correspondence.

THOMSON-HOUSTON PLANTS IN THE WEST.

The Chicago office of the Thomson-Houston Co. reports the following sales of isolated plants: Schneidewend & Lee Co., Archer avenue and Halsted street, Chicago, 300 incandescent electric lights; Johnson Locke Mercantile Co., San Francisco, Cal., for the California Pumice Co., at Napa, Cal., 50 incandescent lights Fecker Brewing Co., 371 Dudley street, Chicago, 50 incandescent lights; Chicago Anderson Common Brick Co., town of Lyons, near Chicago, 13 arc lights; the McCormick Harvester Machine Co., an order for a 16 arc light second hand outfit for blacksmith shop; Compound Lumber Co., 70 incandescent lights for Hegewison, Ill.

THE ROBERTS ELECTRIC LAUNCH AT TORONTO, CAN.

The staid everyday citizen who happened to be out boating on the bay on Saturday afternoon, Oct. 25, says the *Toronto Mail*, was doubtless startled by the strange spectacle of a good-sized launch carrying fourteen men about with wonderful speed, apparently moved by some occult and mysterious power. There was no smokestack, no oars, and only a muffled whirr told that some machine furnished the power. The launch was driven by the Roberts storage batteries, and among the passengers were Mr. W. Roberts, the electrician; Mr. A. T. Anderson, Mr. Wilson, Mr. E. Radway, marine engineer, and representatives of the press. The yacht was built by Mr. Lorsch, of the Excelsior boat-house, from designs furnished by Mr. G. H. McFarlane, of the Roberts Storage Battery and Electrical Construction Company, 46 Adelaide street, west. The power was furnished by the Roberts storage batteries, driving a Kay shunt wound three-horse power motor. When connected in a series the batteries were capable of developing four-horse-power and driving the yacht at a speed of eight miles per hour. Coupled in multiple form the motor will develop three-horse-power, and the charge will last a whole day. The storage jars were of rubber, so that there was no danger from breakage, and the Toronto Electric Light Company will charge the cells at the rate of 20 cents per hour. With Mr. Roberts at the throttle, as the miniature switch might be termed, the yacht ran to Hanlan's point and back in 28 minutes. The screw was stopped, reversed, turned ahead by simply moving the switch. The trial trip was very highly satisfactory, and upon landing, Mr. McAulay, of Kingston, gave an order for a similarly equipped boat.

EMPIRE CITY ELECTRIC CO.

Driven by the great increase of business to enlarge its facilities, the Empire City Electric Co., of 15 Dey street, has now annexed the fine adjoining store to the west, and has broken an archway through for communication. The old and new stores are being handsomely decorated. The annex will be laid out in banking house style, for the bookkeeping purposes of the concern, and will be one of the most tasteful electrical offices in town. In spite of his recent severe illness, General Madden has been giving the extensions his personal care and direction.

JAS. W. QUEEN & CO.

The above firm have issued a very pretty little folder in tints, on their Ayrton & Perry magnifying spring ammeters and voltmeters. It is addressed to electrical engineers and central station superintendents, and dwells forcibly upon the chief characteristics of the instruments referred to.

ELECTRIC WELDING.

The Thomson Electric Welding Co., of Boston, Mass., is putting in an electric machine to weld ¼ inch steel for wire and rods for the Cleveland Rolling Mill Co. Mr. A. M. Bullard is superintending the work. A machine was put in by this company for the Rogers Typograph Co. and is giving great satisfaction.

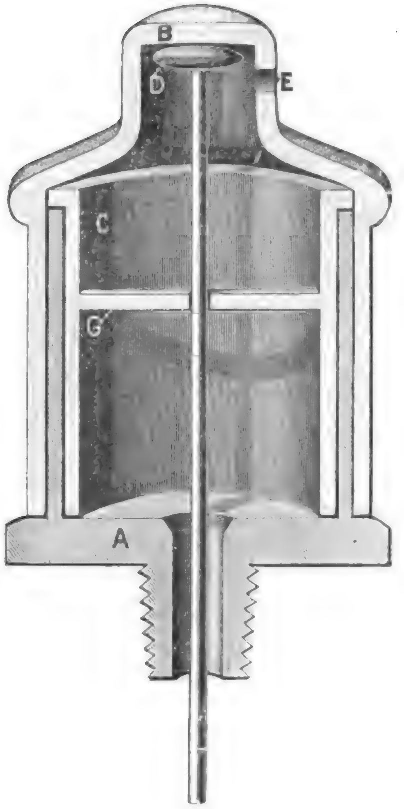
THE ECLIPSE CLUTCH WORKS, BELOIT, WIS.

The manufacture of friction clutch pulleys and other power transmission machinery, formerly conducted as a branch of the business of the Eclipse Wind Engine Co., of Beloit, has now been transferred to the Eclipse Clutch Works, a separate concern, by which it will now be actively pushed.

POWELL'S ELECTRIC CAR GREASE CUPS

An electric car motor being under the car floor, it is an important factor in such service that lubrication to the journal bearings should be prompt and quickly accomplished. The Powell car motor lubricator is expressly devised to accomplish this without a loss of time, even when the car is in motion. The cup, which is illustrated in the accompanying engraving, is constructed with a removable charging case, and is instantly removed and replaced when required.

To refill the cup, the hood B is pulled off and the case C withdrawn by inserting the finger under the guide bar G. The cup is then filled, the guide bar with its friction rod, replaced, and the cover returned. As the latter slides down the whole length of the chamber A, there is no possiblity of the cover being lost or



The Powell Electric Car Grease Cup.

shaken off while the car is in motion, and all dirt is rigidly excluded from the bearings.

This cup is manufactured by the Wm. Powell Co., of Cincinnati, O., the makers of the well known "Signal" dynamo oil cups, and sight feed lubricators.

THE BUFFALO ELECTRICAL SOCIETY.

This society continues to do a noble educational work, and has just issued its programme for the season of 1890-1. It embraces a variety of interesting topics, and the list of lecturers includes such well known names as A. C. Terry, W. Finn, Frank Kitton, M. Buell and F. P. Jones. The society is richly deserving of local support and of good wishes everywhere.

OBITUARY.—MR. H. H. JOHNSON.

We regret to announce the death of Mr. H. H. Johnson, who has been for a number of years superintendent of the Hartford Electric Light Co. Mr. Johnson was taken down with typhoid fever a little more than a week ago, and from the very first his life was despaired of. His career as a station superintendent has been a very successful one, and he was deservedly popular, having endeared himself by his uniform courtesy and good fellowship with a host of men who had occasion to have business dealings with him. His place will not be easily filled, and many in the years to come will miss his cheerful smile and hearty welcome. His funeral took place last Wednesday and was attended by large numbers of his friends, and numerous floral offerings were sent as the last signs of affection and good will.

NEW ENGLAND TRADE NOTES.

The Billings & Spencer Co., of Hartford, the well known manufacturers of drop forgings for electrical purposes, are building a large addition to their factory. Their business in commutator bars has never been so large as at present, and they have received some very large orders for these goods.

The Jewell Belting Co., of Hartford, have nearly completed their large addition to their present quarters. The addition consists of a large four-story brick building adjoining their present factory. The Jewell belt is becoming very popular for electric work, and they have at present on their books a number of orders for various electric light and power stations from all parts of the country.

The Standard Electric Time Co., of New Haven, Conn., are developing a large business in their Warner system of electric time clocks, and have recently licensed The Standard Electric Time Co. ,of Seattle, to operate in the States of Washington and Oregon. This company has been organized with a capital of $25,000 all subscribed and has already ordered about a ton of clocks, consisting of two regulators and 50 dials.

The Bryant Electric Co., of Bridgeport, have secured the exclusive rights of manufacture of double pole switches under the patents of W. B. Cleveland, which consists of the spiral spring attachment for the quick make and break of contact, out of control of the operator after passing a certain point. This ends the litigation on these patents.

Mr. O. S. Platt, of Bridgeport, Conn., is having quite a success with his switch, which he recently put on the market. The switch has met with general approval and Mr. Platt has had to double his capacity to keep up with the growing demand.

NEW YORK STATE NOTES.

The American Electric Supply Co., of 226 Pearl street, Buffalo, who have been in business only a few weeks, are enjoying unusual prosperity. They have already furnished a fine isolated plant in the building of The Snow Steam Pump Co., East Buffalo, are putting in a central station plant at Fredonia, N. Y., and have secured the contract to wire the new Cornell library building at Ithaca—which, by the way, is to be a $1,000,000 structure.

The Electric Engineering and Supply Co., of Syracuse, whose suite of offices in the Everson Building is equipped with everything, from a long-distance telephone to a live, pushing manager, is doing a rattling business. They are contemplating securing more commodious quarters for their warerooms, which, by the way, are centrally located in a three-story building on Water street. Syracuse and locality have long felt the want of a concern that will combine electrical engineering of the highest class with a full stock of staple supplies and specialties, and the city is certainly to be congratulated on now having such a company under the management of Mr. F. H. Leonard, whose past work for the Thomson-Houston Company in New York State is widely known.

ST. LOUIS TRADE NOTES.

The St. Louis Car Co. have erected a new building during the past summer to provide additional facilities for building electric cars. They are now building 30 electric cars for the Mound City R. R., of St. Louis; 30 electric cars for Quincy, Ill.; 15 for Springfield, Mo.; 15 for Rockford, Ill.; 15 for the Storage Battery Street Railway, New Orleans; 12 for Springfield, Ill.; 5 additional cars for the Union Depot R. R., of St. Louis, and 2 for Joliet, Ill.

The Laclede Car Co. are finishing up an order of 100 closed cars and 60 summer cars for the Minneapolis Electric Railway. They are also building 12 electric cars for Duluth, Minn.; 47 electric cars for Cincinnati and 13 electric cars for Findlay, O.; 14 electric cars are now being forwarded to Dallas, Tex. They are also building 3 cars for the Pneumatic Railroad, at Washington, D. C.

The Brownell and Wight Street Car Co. are building a number of street cars for electric railways at Louisville, Ky., Ft. Worth, Tex., and Duluth, Minn.; also 80 grip and 50 coaches for the new cable equipment of the St. Louis railroad—the Broadway line.

Mr. D. W. Guernsey, the St. Louis representative of the Edison electric railway system, has sold four 3 h. p. railway motors to the National Unicycle Elevated Railway Construction Co., for their motor cars.

B. J. Arnold, the St. Louis representative of the Thomson-Houston Electric Company, has closed contracts with the Missouri Car and Foundry Co. for 12 arc lights, with the East St. Louis Packing and Provision Company for 300 incandescent lights, direct current, and with the Osage Mining Company, McAllister, I. T., for a 20 h. p. motor which will be used for pumping in a coal mine, also, 1,300 incandescent lights for Desoto, Mo.

Electrical Engineer.

VOL. X. DECEMBER 3, 1890. No. 135.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—III.

BY HERBERT LAWS WEBB.

A VERY convenient form of galvanometer, illustrated in Fig. 9, is the tripod astatic. This galvanometer is much less expensive than the square pattern, and also more adapted for carrying about, as it can be packed in less space, making it a very useful instrument where much outside work has to be done. It has only two coils which are generally wound to a resistance of about 5,000 ohms. The mirror with the upper needles is suspended in the centre of the coils, and the lower needles with the vane hang just below the coils; the terminals, of which there are two only, instead of eight, are placed at the rear of the case. This form of galvanometer is not so sensitive, of course, as the

FIG. 9.—TRIPOD ASTATIC GALVANOMETER.

pattern first described, but if properly set up will give very good results, and is amply sufficient for all ordinary work, with the exception, perhaps, of testing very short lengths of heavily insulated cable. A little extra care is required in setting up the galvanometer, as it is not provided with a spirit level; if no small level is at hand to assist the eye, the best plan is to watch the mirror until it hangs exactly in the centre of the coils.

Another form of reflecting galvanometer, much used for outdoor work and carrying about from place to place, is the portable dead-beat instrument, illustrated in Fig. 10. The dead-beat arrangement was invented by Sir Wm.

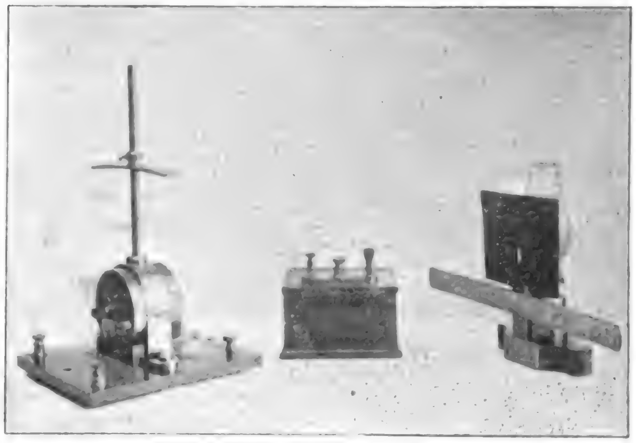

FIG. 10.—PORTABLE DEAD-BEAT REFLECTING GALVANOMETER SET.

Thomson, to do away with the inconvenience of waiting for the needle to cease oscillating before taking up a settled position on the scale. The mirror with the small needles at the back is suspended by a short fibre in a brass tube; the space in which the mirror hangs is transformed into a small air-tight chamber by two glasses, one set in the main part of the tube behind the mirror, and the other in a small cap which screws on in front. The air confined in this small chamber dampens the movements of the mirror, which, instead of oscillating back and forth for some time when current is turned on and off, turns steadily to a certain angle, or back to zero, and stops dead. The small galvanometer is shown with its lamp and scale and combined high resistance and shunt, forming part of a compact portable set of instruments for outdoor testing.

This form of galvanometer is by no means to be recommended for general work; it is not sensitive, and the readings, under certain conditions, are not any too accurate. Magnetic disturbances affect it very considerably, even if the moving iron be some distance removed from the galvanometer. To overcome this difficulty, which is present with a non-astatic instrument almost everywhere except in the open country, the magnetic shield, shown in Fig. 11, has been designed and has proved very useful. It consists simply of a hollow case of tin plate made in two sections so as to enclose the galvanometer coil, and filled up with iron filings. This arrangement forms a very efficient screen for magnetic disturbances under most circumstances, but in some cases it has failed to keep the needle from being affected.

SHUNTS.

THE most important accessory to a galvanometer is, of course, the shunt. This consists of a set of resistance coils placed in a suitable box or case provided with terminals by means of which it may be connected with the galva-

nometer and the source of current. The coils form a path outside the galvanometer for the current which will be divided between the shunt and the galvanometer coils in proportion to their resistances. The use of a shunt is very necessary with a delicate galvanometer because its sensitive-

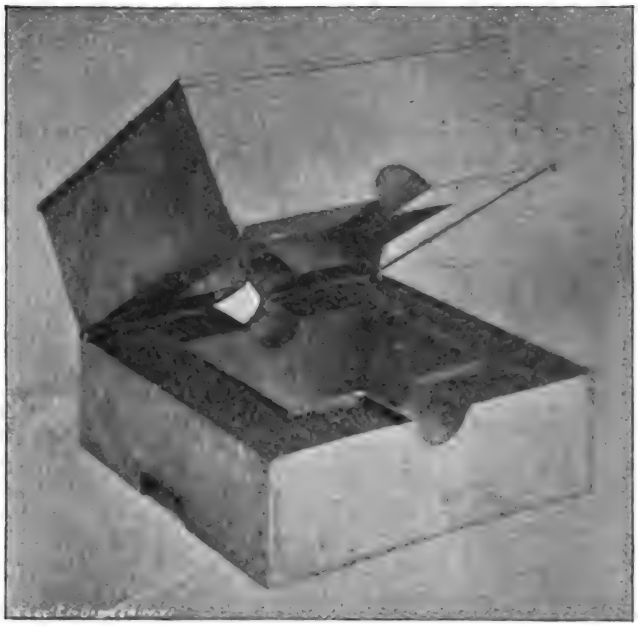

FIG. 11.—MAGNETIC SHIELD.

ness is so great that it will only measure directly very feeble currents; consequently when the deflection to be produced is likely to be beyond the range of the scale only a fixed proportion of the current is allowed to pass through the galvanometer, and the deflection obtained is multiplied by the value of the shunt.

The multiplying value of a shunt is equal to the sum of

FIG. 12.—SHUNT BOX.

the resistance of the galvanometer and that of the shunt divided by the resistance of the shunt, thus $\frac{G + S}{S}$.

For instance, if we have a galvanometer of 9,000 ohms resistance shunted by a coil of wire having a resistance of 1,000 ohms, substituting these figures for G and S we have, $\frac{9{,}000 + 1{,}000}{1{,}000} = 10$. The multiplying power of the shunt would therefore be 10, and all deflections obtained on the galvanometer with this shunt in circuit would have to be multiplied by ten in comparing them with deflections obtained without any shunt in circuit.

The shunt box generally contains three coils having, respectively $\frac{1}{9}$th; $\frac{1}{99}$th and $\frac{1}{999}$th the resistance of the galvanometer coils. The deflections obtained with the shunts must be multiplied by 10, 100 and 1,000, according to the coil used. Figs. 12 and 13 illustrate different forms of shunt boxes intended for use with Thomson galvanometers.

It is sometimes necessary or desirable to make up a shunt of some other multiplying value than ten, one hundred or one thousand, and this is an easy matter if a set of adjustable resistance coils is at hand and the resistance of the galvanometer is known. The resistance of a shunt having a multiplying value n is expressed as follows, $S = \frac{G}{n-1}$. Thus, if our galvanometer has a resistance of 8,000 ohms, and we wish to make a shunt having a multiplying value of five, the resistance to be given the

FIG. 13.—SHUNT BOX.

shunt would be $\frac{8{,}000}{5-1} = 2{,}000$ ohms. If we find the $\frac{1}{999}$th shunt does not reduce our deflections sufficiently, and we desire to make a shunt having the multiplying value of 5,000 instead of 1,000, then $\frac{8{,}000}{5{,}000-1} = 1.6$ ohms, or, to be more accurate, 1.6003 ohm would be the resistance of the shunt required.

The shunt should be placed close to the galvanometer so as to be as nearly as possible subject to the same temperature, and should be connected to it by short thick leads in order not to place any additional resistance between the shunt and the galvanometer.

ELECTRICITY AT RUTGERS COLLEGE.

Last commencement the trustees gave $2,500 for apparatus for the electrical engineering department, and this sum is being judiciously expended by the very competent professor in charge, Dr. F. C. Van Dyck. A much larger sum is needed, but the trustees cannot now see their way clear to give any more at present. A permanent fund should be raised for the department, it is claimed, so that it may meet all the demands that now come upon a new section of this character.

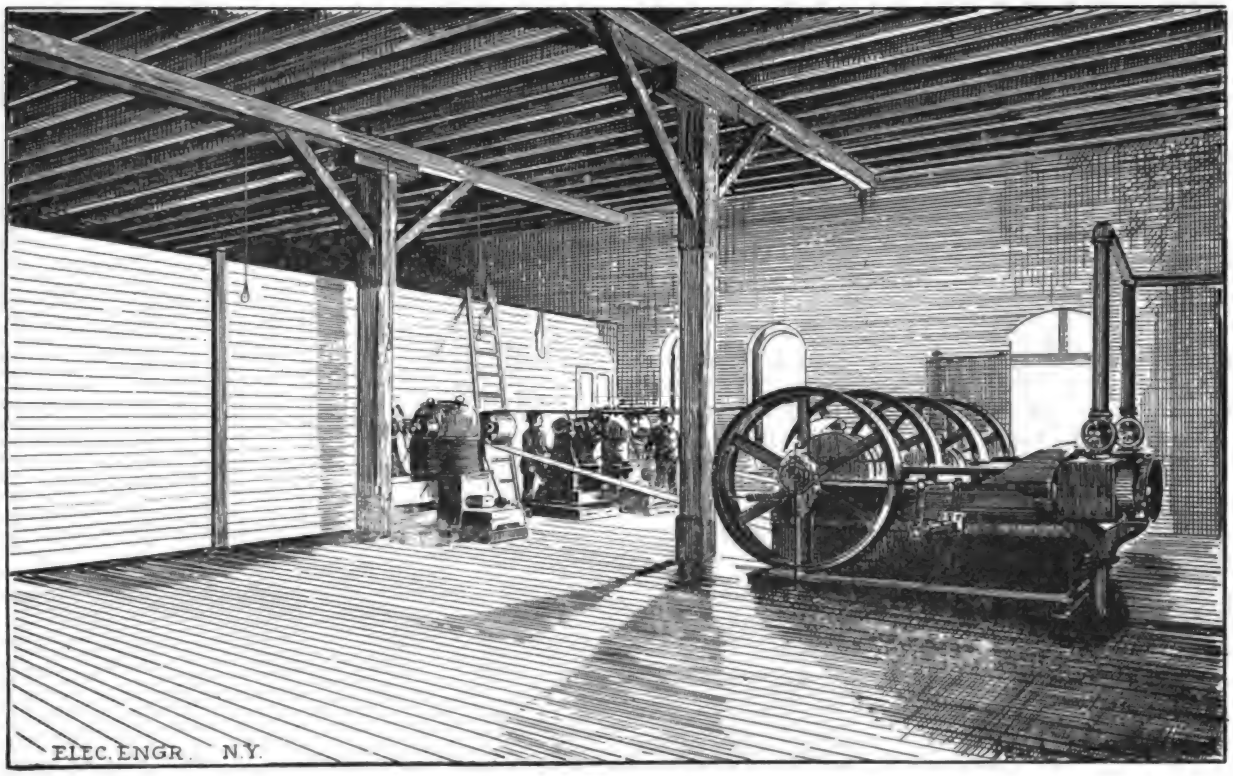

FIG. 1.—STREATOR, ILL., ELECTRIC RAILWAY POWER PLANT.

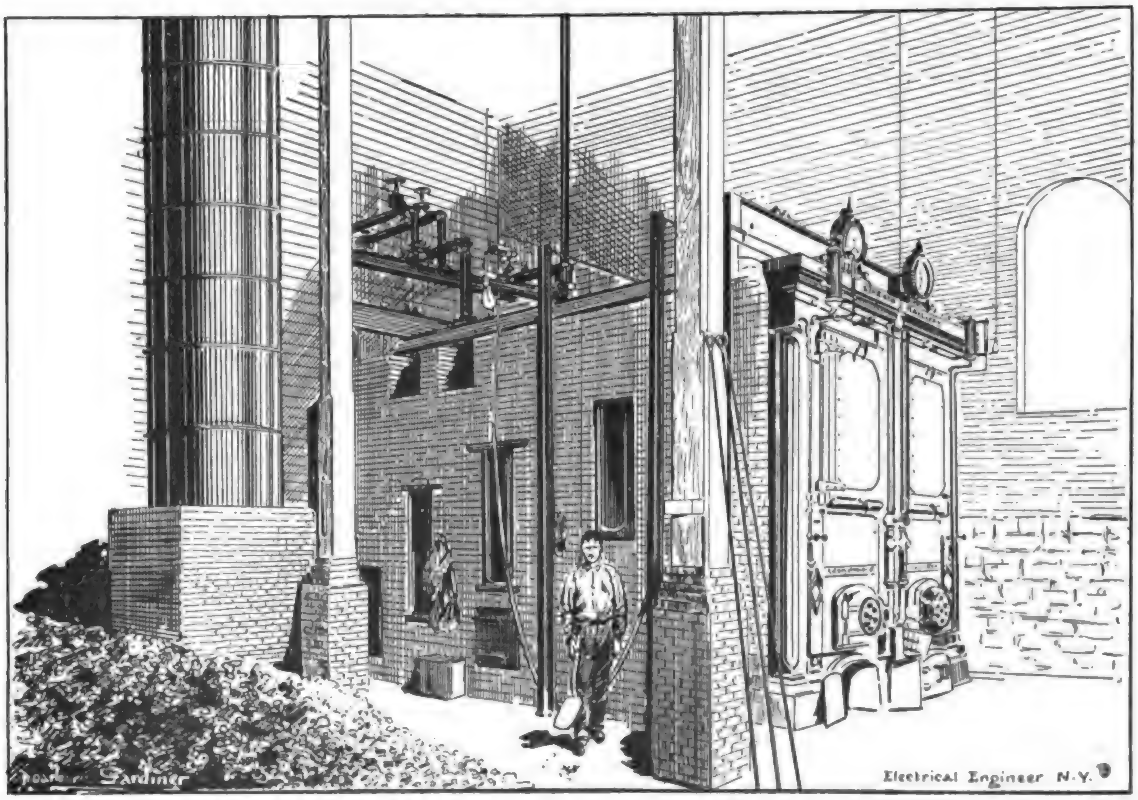

FIG. 2.—BOILER PLANT—STREATOR, ILL., ELECTRIC RAILWAY.

THE NEW ELECTRIC STREET RAILWAY AT STREATOR, ILL.

BY W. F. COLLINS.

HAVING recently had the pleasure of inspecting personally the plant, rolling stock, etc., of the new electric road of Streator, I am glad to furnish a few details and views of that interesting installation. The road is of the Thomson-Houston system, and is owned and operated by the Streator Railway Co., of which P. F. Barr is the president, D. Heenan, vice-president, W. Reeves, secretary, J. C. Barlow, treasurer, and W. Miller, manager.

The station, shown in Fig. 1, comprises two 125-h. p. Armington & Sims high-speed engines, belted direct to two 500 volt Thomson-Houston generators of 80-h. p. capacity each, compound wound and maintaining a constant difference of potential on the circuit irrespective of variations in the load. Two Babcock & Wilcox boilers, each of 125-

h. p., Fig. 2, provide the steam for running the engines. Two Buffalo steam pumps, manufactured by the Buffalo, N. Y., Steam Pump Company, and a Hoppes feed water heater, Fig. 3, of capacity sufficient for the two boilers, complete the steam equipment.

The whole power plant was furnished by the well-known Pond Engineering Co., of St. Louis, and erected under the personal supervision of Mr. Albert Blanchard, the Chicago manager of the company.

The electrical equipment was supplied by the Thomson-Houston Electric Co., and Mr. James H. Garrett, electrical engineer of the Northwestern Thomson-Houston Co., had charge of this part of the work and carried it out in the most praiseworthy manner. The road is at present operating six motor cars, but an increase in cars and an extension of the road will very shortly follow. The cars were built by the Laclede Car Company, of St. Louis, have 16 feet bodies and are elegantly finished. They are supported on Hubbard trucks, manufactured by the McGuire Manufacturing Company, of Chicago, and each car is fitted with two 15-h. p. Thomson-Houston motors. The power station is situated near the centre of the road which runs out on either side of it on North and South Illinois streets. From the station the main track runs up Main street and then branches out on each side on North and South Bloomington streets.

The whole road was built and equipped under the eye of Mr. Walker Miller, the manager of the company, and to the great care exercised by him and his intelligent supervision of everything in track, power house, electrical equipment, etc., to all the minor details of the work is due the great satisfaction and success which this new road has given and enjoyed. The franchise owned by the company also includes light and power, and it is probable that the station will shortly be extended to furnish this class of service in the very near future. The plant is likely, in fact, to present an interesting study as one combining all the various classes of electric light and power service, and as an example of the successful manner in which net revenues may be increased to the highest point by this method of operation.

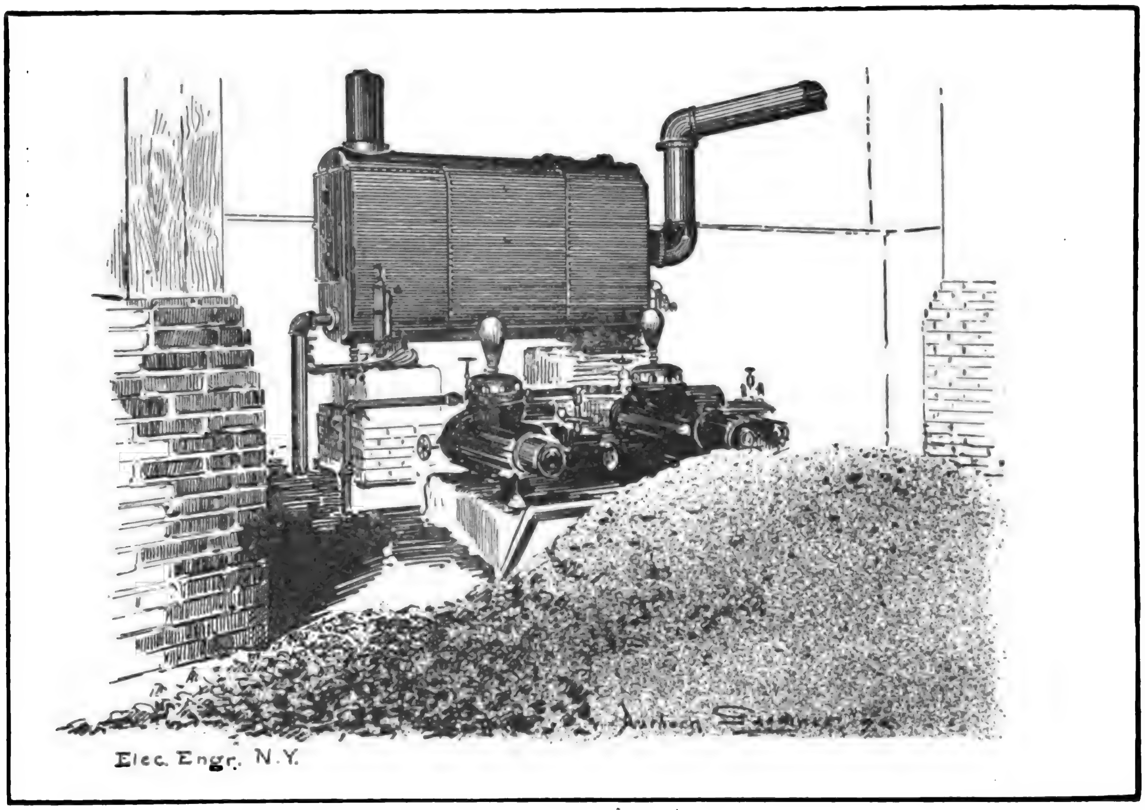

Fig. 3.—Hoppes Heater, Streator, Ill., Electric Railway Plant.

AN ELECTRICAL LOAD EQUALIZER.

BY C. O. MAILLOUX.

The task allotted to the steam engine in electric railway work is not an easy one. It would indeed be difficult to contrive a more crucial test than such work affords of the regulating qualities and mechanical endurance of an engine. The load is incessantly undergoing fluctuations which are not only sudden, but extremely severe. An interval of a few seconds often marks the jump from light load to the maximum capacity of the engine, or else a sudden release from full load to no load. Yet, under these trying conditions the engine is required by the electrical engineer to satisfy in turn and collectively the three important requirements of close regulation, great mechanical endurance and high economy. It is almost needless to say that these three qualities have not yet been reconciled under such conditions. In electric railway practice, it is not uncommon to find a 100 h. p. engine carrying an average load of from 40 to 60 h. p. The fact that the load is likely to jump up now and then to 100 or 120 h. p. makes this margin necessary, for without it, the first two qualities, regulation and endurance, could not be secured. As for the third quality, it is of necessity sacrificed. Even under this compromise the durability, as experience shows, is not by any means an assured quality. Practice is indeed drifting to the conclusion that a further compromise must be made to favor still more the second at the expense of the first quality, and engines of slow-speed types are coming into use. This change also favors the third quality incidentally, but only to a remote degree.

The question of economy in electric railway working is not altogether one of engine type or capacity for the

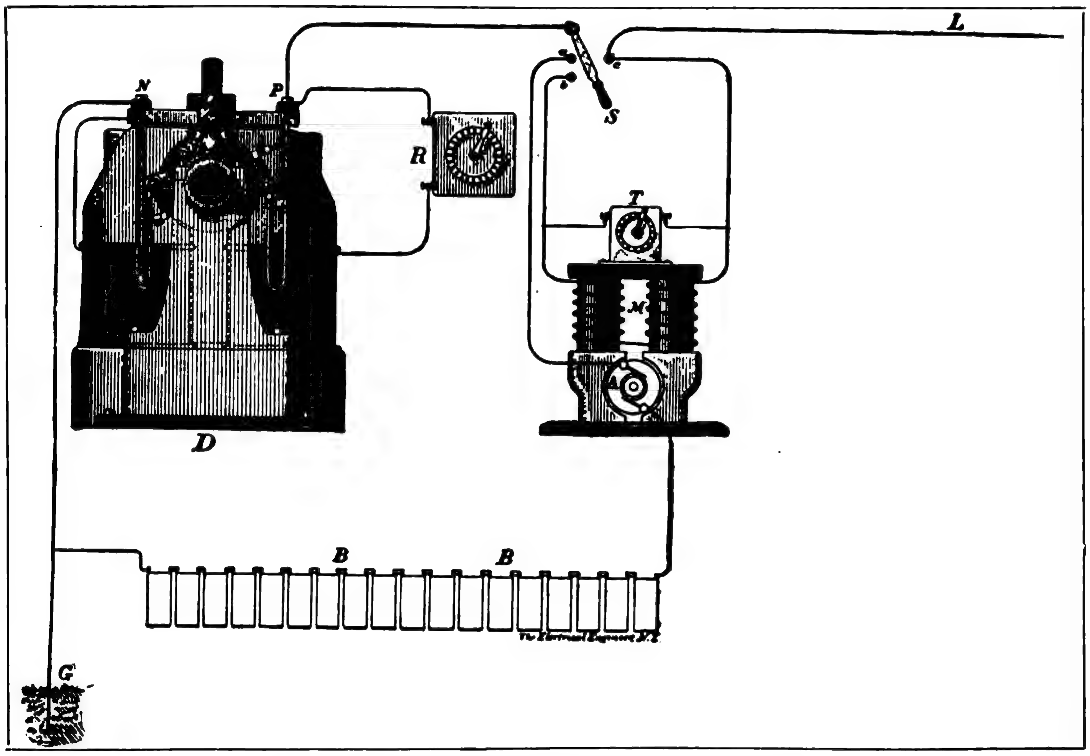
particular case. The efficiency of an engine running light is zero; that of an engine overloaded and taking steam during the entire stroke is also very low. Between these two extremes there is a point of maximum efficiency, corresponding usually to the nominal rated capacity of the engine. If the engine can be worked at this capacity, and if fluctuations much above or below this load can be avoided, the conditions will no longer be incompatible with, but will become favorable to, efficiency. With a steadier, more uniform load, the problem of speed regulation of course vanishes, while that of durability becomes greatly simplified.

It was this reasoning which led the writer some time ago to devise a method of equalizing the engine-load by electrical means, and of rendering the engine independent, to a great extent, of the fluctuations in power consumption on the trolley lines. The method aims to accomplish electrically for the dynamo what the fly-wheel does in a mechanical way for the engine. It provides the circuit with a kind of reserve fund of energy that is ready to instantly appropriate any surplus of electric power when the load is light, or make up the deficit when it is heavy.

an electric motor supplied from the trolley circuit. This armature is made of low resistance and capable of carrying a large current.

The cells B B may be of any form, although the Planté type is preferable on account of its simplicity and its ability to withstand severe rates of charge and discharge without injury. These cells need be but of small capacity or only partially formed, since the storing capacity required of them is very small, as will be seen. The number of cells required will depend on the voltage of the circuit. For a 500 volt circuit, which is the usual standard in electric railway practice, a series of about 225 cells would be required. The facilities for adjustment are such, however, that the number of cells may be varied considerably without detriment. It will be seen from the connections that so long as no current is consumed on the line the armature A will have its field demagnetized. It therefore generates practically no E. M. F. and constitutes merely a dead resistance.

By the passage of current to the trolley line the field magnet coil M is excited and made to produce a definite



Mailloux's Railway Power Equalizing System.

The method consists in connecting to the terminals of, and in parallel with, the ordinary generating dynamo D supplying feeder circuit or trolley line L, a compensating circuit, including a series of storage-battery cells B B, and the armature A of a small supplemental generator. The field magnet coil M of this small generator consists of a few turns of large wire similar to the series coil of a compound-wound machine. This coil is not included with the armature in the compensating or branch circuit, but is placed in the circuit leading to the trolley line. Consequently when the circuit switch S is thrown to the left, thereby connecting the dynamo to both points *a* and *b* and closing both the main and branch circuits, the current sent out to the trolley line L will pass through the coils M, suitable means, such as a shunting rheostat T, being provided, whereby the effectual ampere-turns due to a given current may be adjusted.

The armature A of the small machine is driven at constant speed by power obtained from any convenient source, as, for instance, the same engine that drives the main dynamo D. It might be driven by a separate engine or by

amount of field magnetism. It is evident, therefore, that the E. M. F. of the armature A will depend altogether on, and will rise or fall directly with, the current consumed on the trolley lines. This E. M. F. is so "poled" as to add itself to that of the cells B B. It results that when there is no power consumed on the trolley line the voltage of the cells B B will be so much lower than that of the dynamo D, that there will be a large "overflow" of charging current into them. As the power consumed on the line L is increased, the armature A will begin to generate an E. M. F. that will raise the effective voltage of the battery and consequently reduce the charging current, until finally at a certain point, it will stop altogether. If the current now rises above this limit, it will raise the effective voltage of the compensating circuit above that of the dynamo. Consequently the battery will now begin to discharge current into the circuit just as if it were another dynamo coupled in parallel with the main dynamo D. When this point is reached if the field magnet of the small machine is still much below saturation, the further increase of the current may raise the effective E. M. F. of the compensating circuit con-

siderably higher than that of the dynamo. It might seem, therefore, that the dynamo D is likely to be overbalanced and converted into a motor.

There is another important factor that intervenes here, however, viz., the polarization of the battery. It is well known, as one of the disadvantages of storage batteries, that their potential difference is diminished as the discharge current is increased, partly owing to their internal resistance and partly to the effect of polarization, the latter being especially marked with heavy discharges. It follows from this that the effectual voltage of the compensating circuit when the discharge begins, will not rise in proportion to the E. M. F. added by the armature A, but at a rate which is slower the greater the current; consequently, when a certain current value is reached the rise in effective voltage will be much slower. If this does not suffice to limit the rise of E. M. F. made in the compensating circuit, the adjustments can be made to lower the saturation point of the field cores, so that the bend of the characteristic may correspond to a lower current. This can be done by suitably proportioning the iron in the field magnet cores; or, with a given machine, by varying the effectual ampere-turns, by means of the shunting rheostat T, the speed being changed so as to preserve the same total range of supplemental E. M. F. Thus it is seen that the rise of effective E. M. F. in the compensating circuit can be limited at any desired point.

If the limit is the same as the E. M. F. of the main dynamo, then the compensating circuit will supply about half the current required for the trolley line. If the limit is a trifle higher the compensating circuit will supply slightly more than half. If the limit be sufficiently high the compensating circuit will assume practically the whole load, and relieve the dynamo and engine.

It is not necessary, as might appear at first, that the field cores of the supplemental generator should be laminated, to make the apparatus sensitive and responsive to sudden fluctuations. Advantage, again, is taken here of the polarization of the batteries. It requires a minute interval of time for a storage battery to polarize or depolarize. This interval will practically balance the time required for the rise or fall of magnetization.

As a case illustrating the operation of the above method let us take a dynamo of, say, 50,000 watts capacity, supplying a railway circuit at 500 volts pressure. Under present practice the average load put on such a machine would scarcely exceed 60 amperes, and the engine would be of about 100 h. p. capacity, if not more. Instead of this, an engine of about 80 h. p. would be used, and the average load would be made at least 90 amperes. The compensating circuit would then be so adjusted that whenever the current consumed on the trolley line would fall much below 90 amperes the main dynamo would overflow into the battery. If the consumption ceased altogether, for a brief instant, as so often occurs, the dynamo and engine, instead of running empty, would run at nearly the same output, the whole current being sent into the batteries.

As the current increased on the trolley line the overflow would diminish, and, at a little below 90 amperes, it would cease. Any increase above 90 amperes would cause the battery to discharge and help the dynamo. The greater and the more urgent the demand for assistance the more promptly and liberally will the supply be given. Not only will the supply provide for the excess of current required above the 90 amperes furnished by the dynamo, but, as shown above, it may be made to relieve the dynamo itself either partly or wholly.

Let us now analyze the action of the compensating circuit. When there is no current on the trolley circuit the current sent into the batteries will pass through the armature A as if it were a dead resistance. When current is consumed on the line, however, the magnetic field becomes excited, and the charging current now operates the armature A as a motor. The amount of energy thus re-converted is not large, however, since the charging current is large only when the counter E. M. F., generated by armature A, is small, and vice versa. When the working current rises above the adjusted limit of 90 amperes the batteries begin to discharge, and the armature A then becomes a dynamo.

Let us assume that the load jumps up suddenly to double its average value, or 180 amperes, and remains so for five minutes. Such severe fluctuations are not infrequent, although they scarcely persist, as a rule, longer than from a few seconds to a minute. Let us assume that the compensating circuit will carry the excess of 90 amperes, making, at, say, 501 volts, an output of 45,090 watts. If we assume that the battery will so polarize at this rate of discharge that it cannot be counted upon for more than, say, 1.8 volts per cell, we have, as the available potential difference of the battery, $225 \times 1.8 = 405$ volts. The armature of the supplemental generator will therefore need to supply $501 - 405 = 96$ volts. The amount of energy which the supplemental dynamo must provide will consequently be $96 \times 90 = 8,640$ watts. The battery supplies the rest, or $405 \times 90 = 36,450$ watts.

If the same engine drives both dynamos, we see that a rise of 100 per cent. in the current load will only cause a rise of 20 per cent. in the output of the engine. The battery furnishes the other 80 per cent. If, however, we consider that the engine is likely to slacken its speed slightly when the fluctuation occurs, or if we adjust the supplemental dynamo to a slightly higher limit of E. M. F. the main dynamo D will be partly relieved of its own load.

In other words, the conditions can be made such, that the main dynamo will carry, let us say, only 80 amperes, and the compensating circuit 100 amperes. The combined load of both dynamos will now be $80 \times 500 = 40,000$, and $100 \times 96 = 9,600$; total, $40,000 + 9,600 = 49,600$ watts, or only 4,600 watts, or 10 per cent. more than the average working rate of the main dynamo. The battery will supply $100 \times 405 = 40,500$ watts or 90 per cent. of the energy required in excess of the average load.

The storage capacity required to compass such a severe and prolonged fluctuation is naturally a question of importance. A current of 100 amperes for five minutes represents a total of 500 ampere-minutes or $\frac{500}{60} = 8.33$ ampere-hours. Hence, if each cell has a storing capacity of only 10 ampere-hours it will have margin sufficient for all contingencies. Even if doubled, the capacity per cell would still be only about one-eighth to one-tenth of the capacity of the cells used in storage battery traction. For a 50,000 watt dynamo the series of cells required would be equivalent in storage capacity to about one-fourth of the battery usually put into each storage battery car.

With the above method of equalizing the load, the part assigned to the engine becomes wonderfully easy and simple. The engine no longer is required to anticipate and provide for jumps in the load. It no longer has the responsibility of keeping the current pressure steady, or its supply adequate. Its load becomes so nearly uniform that the first of the three requirements noted in the beginning, close regulation, is no longer of primary but is of remote importance, while the second and third are at the same time greatly facilitated. The slow-speed, double-valve engine, whose superior economy is conceded, now becomes not only permissible, but eminently practicable. We must also bear in mind that this method further favors economy by materially increasing the working capacity of a given plant, obviating, as it does, the necessity for the margin required under the old way, to compass the fluctuations of load. The method is, it is evident, applicable to all systems of the constant potential description, and is adaptable to circuits fed either direct or by feeders. The method can be applied to any existing plant without difficulty.

On following the connections in the diagram it will be seen that by turning the switch s to the right, instead of to the left, the compensating circuit is entirely disconnected and the plant operates in the usual way, leaving the engine to bear the brunt of any fluctuations in the power consumed. The method admits of being modified and applied in an indefinite variety of ways which cannot be detailed in this space.

In conclusion it may be noted that accumulators have been for several years used as equalizers or regulators in connection with incandescent lighting circuits. The compensating action thus obtained, however, is much limited in scope and degree. The battery, when unaided, evidently cannot begin to assist the dynamo until the latter has actually wavered perceptibly in potential; and anything like a severe rate of discharge would at once lower the potential below that of the dynamo itself. Hence, even though, in such cases, large cells are used, to reduce the internal resistance and polarization to a minimum, the compensating action is useful only for compassing relatively minute and brief fluctuations. By supplementing the E. M. F. of the accumulators, as is done in the method of the writer, the action is rendered independent of the size of battery used or of the extent and degree of the fluctuations to be compassed. Not only this, but the action does not depend on the loss of E. M. F. of the main dynamo. In fact, as we have seen, the method has for one of its objects to obviate any fall of voltage at the dynamo terminals, while it will easily, if desired, produce the contrary effect, or raise the voltage as the load increases, the same as is done by an "over-compounded" dynamo.

THE HARDING CONDUIT RAILWAY SYSTEM.[1]

BY C. K. HARDING.

The increased interest shown in electric propulsion at the recent convention of the American Street Railway Association, may serve as an excuse for bringing to your notice an improved conduit system, which, although new, is, I think, destined to play an important part in the solution of the problems met in the practical application of electricity, to urban passenger transportation.

My invention embraces as its principal features, a continuous main or supply conductor, insulated and protected in the tubular lower part of a casing, a cross section of which is shown in Fig. 2; and a series of working conductor sections, insulated and supported in the top channel of the casing, with their upper surface exposed and adapted to come in contact with brushes on the car—and electromagnetic contact-making devices, for bringing the conductor sections separately and successively into electric connection with the main insulated supply conductor. These contacts are arranged to be operated by a very small current, derived from the main conductor and extending through branch wires to the adjacent sections, thence through the forward brush to a rheostat on a car, and thence to ground or a return conductor. Fig. 1 shows a working plan of the apparatus; the car itself is supplied with two brushes, at a distance apart, equal to the length of a section of the working conductor, which is laid centrally between the tracks.

The ends of the section are separated by insulating material, and the contact length of each collector is sufficient to overlap this insulation and momentarily receive current from two adjacent sections. As a matter of fact these collectors are intended each to consist of a pair of small wheels running on the supply rail.

Closed at the start, a single one of the switches throws current into one of the sections on which the car rests, and thereafter, whether the car is moving or at rest, the operation of the parts is entirely automatic. Fig. 1 shows three sections of the track and three of the automatic switches. It will be seen that the switch consists of an electro magnet, furnished with an armature which serves to lead the current to a projection from the working conductor.

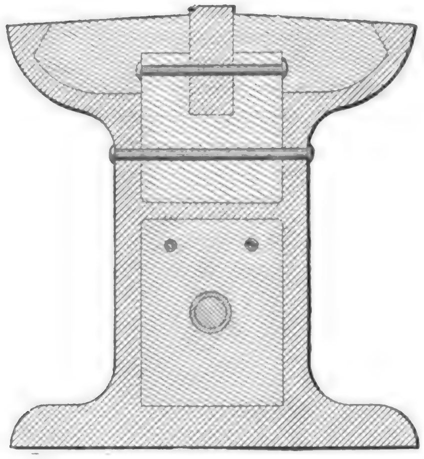


FIG. 2.—THE HARDING ELECTRIC RAILWAY CONDUIT.

The opposite end is turned upward at right angles, and forms another switch the purpose of which will be seen later. The terminals of each magnet are connected, respectively, to the preceding and succeeding sections of the working conductor, to the former through the contact devices shown, and directly to the latter.

Suppose now the switch of the left hand section shown open, to be closed, and the rear collector of the car to be just leaving the section, while the forward collector is just passing from the central to the right hand section shown. Current now passes into the first section of the working conductor through the closed switch, and also through the double contacts connected together by the rear end of the magnet armature through the small connecting wire, to and through the magnet of the middle section, and thence to the car, through the forward part of the forward brush. Thus the magnet of the central section will be energized and its armature attracted closing the switch and letting the current pass from the supply conductor to the central section of the working conductor; but as soon as this switch is closed, the magnet of the first section is shunted around by the low resistance of the direct connection between the supply conductor and the central section of the working conductor.

Hence its armature falls, and in falling breaks all con-

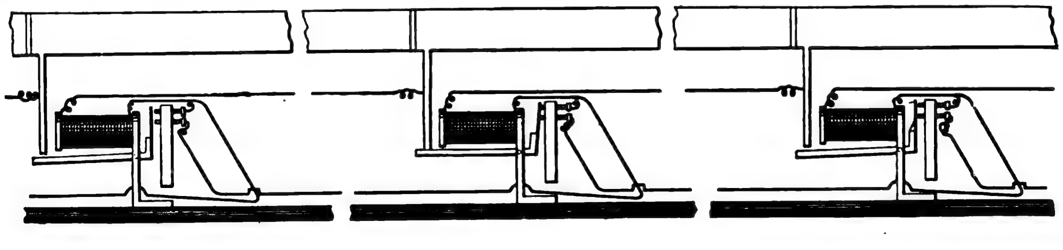

FIG. 1.—THE HARDING ELECTRIC RAILWAY CONDUIT.

1. Abstract from *Street Railway Gazette.*

nection with the first section and leaves it insulated. As the car passes on, this operation is successively repeated through the following sections.

The result of this arrangement is a continuous supply to the sections immediately under the car, the remainder of the working conductor being insulated; consequently there is but little tendency to leakage, and the insulation, usually so difficult, becomes comparatively simple. It will be readily understood, that neither moisture nor a conductor accidentally coming in contact with a section of the working conductor, and grounding it, would cause a short circuit, nor maintain one, after the car had passed; and this is an essential feature.

The simplest form of electro-magnetic contact device would be one, in which the magnets would be in series with the motor; but this would require magnets of a large size, wound with a coarse wire and would require a large amount of current to maintain the contact when the car was stopped, and would be liable to sparking and sticking at the contacts. By the arrangement of the magnets in multiple arc, I am enabled to use small magnets wound with fine wire, and to put the whole contact device in a junction box, Fig. 3, about 3x3x4 in., formed by an enlargement of the lower tube. The whole conduit may be made complete in sections 4 to 6 feet long, and coupled together and put into position in centre of the tracks, without disturbing the track rails already down; the conduit being only about 7 inches high.

It will be seen that the conduit is entirely closed, the main wires imbedded in insulating material in the lower part, and the conductor sections in the upper flaring portion.

The forward part of the car of my system is supplied with a small revolving brush, which sweeps the top of the conduit, and keeps the conductor sections clean.

The safety of this system cannot be questioned, as the only sections that can carry current are those immediately under the car, and protected by it. The path for the return current is through the iron casing and the track rails, thus forming a parallel return, which acts the same as a double trolley system in avoiding inductive interference with telephones.

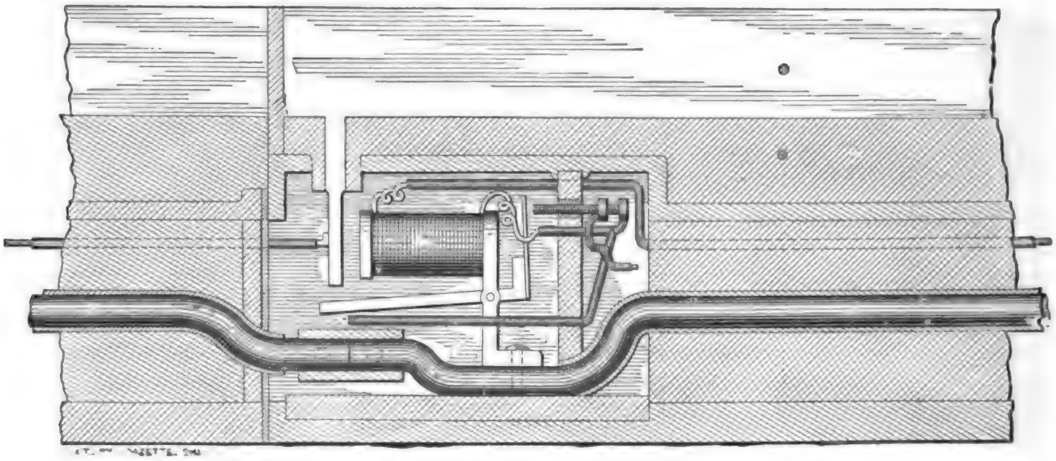

Fig. 3.—The Harding Electric Railway Conduit.

INDIAN SONGS IN THE PHONOGRAPH.

Prof. J. Walter Fewkes says that a phonetic means of studying the language of the Indians and some means of making a record of what is said with accuracy is much desired. The phonograph is such a means, not, perhaps, wholly perfect as yet, but still it serves the purpose. Indian songs, prayers, ceremonials, rituals and speeches by this wonderful instrument are recorded. With the encroachments of whites it is quite certain that in a short time these would be lost were it not for the phonograph. Prof. Fewkes illustrated at the fall meeting of the National Academy of Arts and Sciences the preservation of the songs, etc., of various Indian tribes.

VIBRATIONS OF AN INCANDESCENT PLATINUM WIRE WHEN TRAVERSED BY AN INTERMITTENT CURRENT.

In a recent number of the *Comptes Rendus* M. Argyropoulos describes the following experiment: Take a platinum wire about .7m. long and a fraction of a millimetre in diameter, and pass a current through it until it becomes incandescent; then, if the wire is stretched in a horizontal position and Foucault interrupter is inserted in its circuit, the wire immediately vibrates and becomes subdivided into a series of waves having well-marked ventral segments and nodes. The number of segments is augmented by very slowly decreasing the tension of the wire. On increasing the tension the number is diminished until the incandescent wire vibrates transversely with a single ventral segment at the middle. M. Argyropoulos employed a battery of from 45 to 50 Bunsen cells, and screwed down the commutator until the wire became white hot; then, if the commutator was released, the stretched wire immediately commenced to vibrate.

SILVER REFINING BY ELECTRICITY.[1]

The method is most suitable for the refining of auriferous silver containing about 11 per cent. of gold, the cost in this case being only about 14 cents per pound. The principle upon which the process is based consists in using in an ordinary electrolytic bath anodes of an argentiferous matte, and a thin plate of pure silver as the cathode. The bath consists of a very weak solution of nitric acid containing about one per cent. of the acid. The anodes, which are about one-half inch thick, with a surface of about 13.5 square inches, are placed in muslin bags, which retain the gold, platinum, peroxide of lead, and similar foreign materials contained in the matte. The current used is 150 amperes, and the potential difference between the plates one volt. During the whole period of work brushes are kept moving up and down the silver plates, sweeping off the silver deposited into troughs put for the purpose at the bottom of the bath. These troughs are removed from time to time, and the silver taken out and sent to the furnace. If the matte contains copper, this is dissolved by the nitric acid, but is not deposited on the cathode.

WHEATSTONE BRIDGE MEASUREMENTS WITH TELEPHONE.

Some useful suggestions with regard to the measurement of resistance have recently been made by M. Chaperon, who, in three short papers, discusses the capabilities of the Wheatstone's bridge method when a telephone and alter-

1. *Engineering and Mining Journal.*

nate currents are used in place of the ordinary galvanometer and battery. In spite of the great delicacy of the telephone, measurements made with it are much less accurate than those obtained with a reflecting galvanometer, because the adjustment for minimum sound is never sharply defined.

The ordinary method of double-winding used in resistance coils serves very well for most direct current measurements; but the compensation for induction effects is not nearly perfect enough when rapidly alternating-currents are used, and, according to M. Chaperon, the results obtained under such circumstances are exasperating. The new coils have been wound singly, but so that successive layers are wound in opposite directions, the operation being effected by a specially constructed machine. The current in adjacent conductors thus flows in opposite directions, and self-induction is practically eliminated, while the capacity effect is rendered negligible since contiguous portions of the wire are at nearly the same potential.

JONES' SAFETY DEVICE FOR OVERHEAD CONDUCTORS.

Experience has shown that too many precautions cannot be taken to secure immunity from accident due to broken wires carrying high tension currents, and it is only by constant attention to this important point that the public can be disabused of the idea that the distribution of electricity

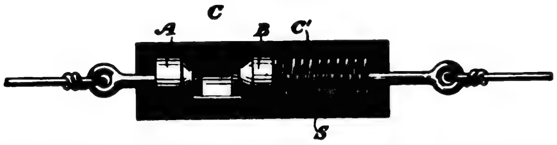

Fig. 1.—Jones' Safety Device For Overhead Wires.

is attended with danger. Among the recent plans devised to secure such safety we desire to call the attention of our readers to a simple safety device, due to Mr. Frank W. Jones, the well-known assistant general manager of the Postal Telegraph Cable Co., of this city.

Although equally well adapted to all high tension circuits, Mr. Jones has sought more particularly to afford a simple way of protecting electric railway conductors, and for this purpose has embodied a method by which a movement of the wire of but an inch from its normal position will cause it to be rendered harmless; thus, should a wire be broken it will have been rendered innocuous before its ends will have touched the ground. This has been carried out in the device shown in the accompanying illustrations, Figs. 1 and 2, and the manner in which they are applied is shown in Fig. 3, in connection with the trolley wire and main conductor of an electric railway.

The safety device, as will be seen, consists of a hard rubber case enclosing two contacts A and B, Fig. 1. This

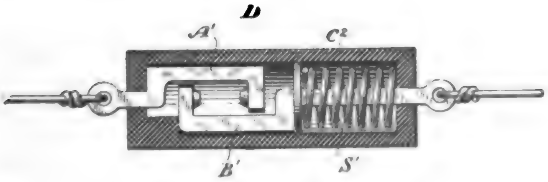

Fig. 2.—Jones' Safety Device For Overhead Wires.

device is shown attached at C with one end connected to the main conductor G W, Fig. 3; the other end is connected to earth. When the conductor is in its normal position, the tension produced by the wire on the spring maintains the contacts A and B apart. Any breakage of the wire G W, however, or any abnormal slacking, causes the spring S to bring the contacts A and B together and thus grounds the conductor. This, of course, is at once noticed at the station where safety devices, such as cut-outs, are applied to prevent destruction of the machine. When the trouble is located and the wires are rejoined, the earth contact is, of course, removed, and the conductor again placed in working condition.

Another form of the device is shown in connection with the trolley wire T W. Here, instead of being placed below, the safety device D is placed above the wire and, as will be seen in Fig. 2, the tension of the branch wire attached to the trolley wire is counteracted by the spring S' so as normally to keep the contacts apart; but upon the breaking of

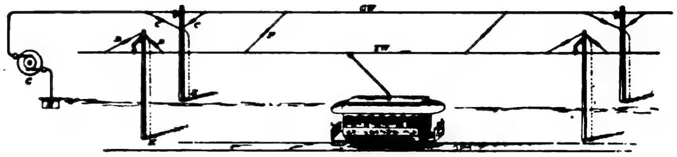

Fig. 3.—Jones' Safety Device For Overhead Wires.

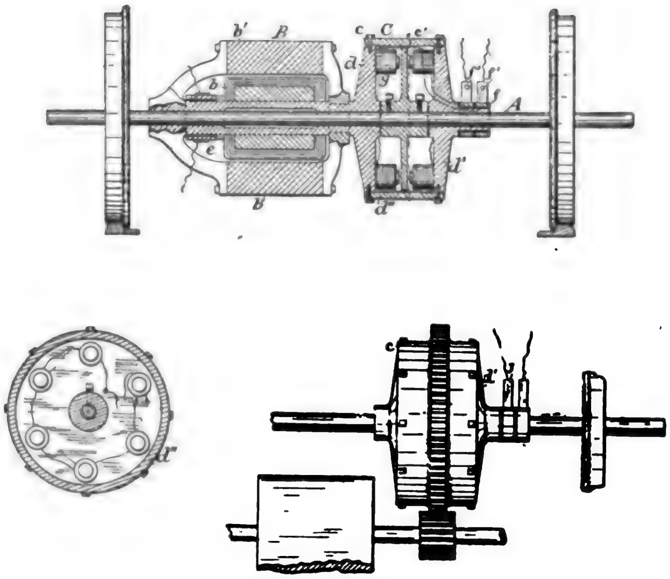
the trolley wire, the spring brings the contacts together and connects the trolley wire directly to earth, thus rendering its ends harmless.

Practical tests with Mr. Jones' device have shown it to answer admirably the purpose for which it is intended, and would seem to make it well worth the attention of electric railway companies.

DEWEY'S ELECTRO-DYNAMIC CAR GEAR.

The reduction in the number of gears necessary to transmit the motion of the motor armature to the car axle has been the aim of many inventors, and has resulted in various forms of mechanical and hydraulic devices. We desire to call the attention of our readers to another method in which this problem has been solved by Mr. Mark W. Dewey, of Syracuse, and which may be termed an electro-dynamic one.

The gear which is shown in the accompanying engravings has the motor mounted loosely on the axle, thus dispensing



Figs. 1, 2 and 3.—Dewey's Electro-Dynamic Car Gear.

with all gear wheels. Upon one side of the armature shaft opposite the end carrying the commutator *e*, is fixed a part of the electric speed transmitting and reducing mechanism C, which is also sleeved loosely on the axle.

The mechanism *c* fixed to the armature shaft consists of two discs *d d'*, facing each other and coupled together at their peripheries by a ring *d''*, encircling them, and bolted to each. Upon the inner faces of each of the discs *d* and *d'* and near their peripheries are fixed a series of electro-magnets *g* and *g'*, with the poles of one series facing the poles of the other series, but a distance apart. The

coils of the magnets are wound so that north poles will face south poles. In order to conduct the current to the magnets, a two-ring commutator *f* is provided, which is insulated from an extension of the hub of the outer discs *d'*, and shown in Fig. 1 in section and in Fig. 3 in elevation.

Between the poles of the magnets *g* and *g'* is arranged a circular plate or disc *c'* of copper, and it forms a part of a hub which is keyed to the axle. This disc and its connection constitute the second part of the power transmitting and reducing mechanism.

It is well known that if a copper disc is rotated near a magnetic needle that the needle will rotate with the disc, but at a slower speed than the disc. This is due to the induction of currents in the copper by the movement of the needle, these currents being such as to oppose that motion of the needle which is the origin of the induction. Mr. Dewey's speed transmitting and reducing mechanism acts on the same principle. The operation of the mechanism is as follows: The armature of the motor rotates the part of the mechanism carrying the electro-magnets at the same speed as the armature, and the disc forming the conductor of the induced currents is both attracted and repelled vigorously in the same direction as the movement of the magnets, but at a reduced speed, depending upon the speed of the magnets and the strength of their magnetism.

It will be noticed that one of the parts of the transmitting mechanism is directly connected to the armature. This is done, if the armature is not sleeved upon the axle or supported by the same, by providing the periphery of the cylinder with cogs as shown in Fig. 3, to work directly in mesh with a pinion on the armature-shaft.

WRIGLEY'S VERTICALLY-ADJUSTABLE DYNAMO SUPPORT.

ONE well marked change which has been brought about by the experience gained in the operation of electric light and power stations and which is manifesting itself strongly in the more modern ones, is in the relative position of the dynamos and engines. While formerly both were placed on the same floor level, economy of operation, as well as convenience in handling, has dictated the placing of the engines on solid foundations, with the dynamos on the floor above. This, of course, necessitates the running of belts vertically to connect the engine pulley with that of the dynamo. As in the horizontal arrangement, means must here also be afforded for maintaining the proper tension of the belt and, on the other hand, for releasing it when the dynamo is not in operation so as to retain the elasticity of the belt. This requires a vertical adjustment

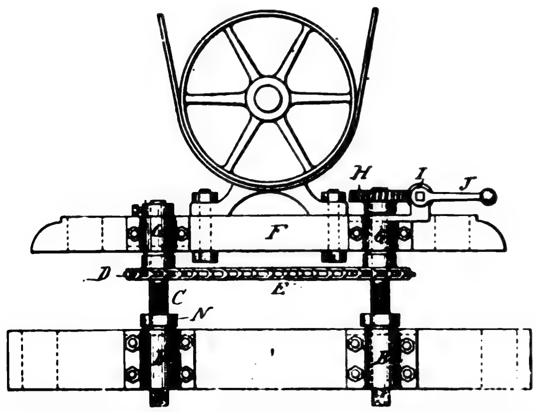


FIG. 1.—WRIGLEY'S VERTICALLY-ADJUSTABLE DYNAMO-SUPPORT.

of the dynamo support, and to effect this in a simple manner Mr. Thomas Wrigley, of Chicago, Ill., has recently designed and patented the dynamo support which is illustrated in the accompanying engravings, Figs. 1, 2 and 3.

As will be seen, the frame A has attached to it the boxes B, which constitute stationary nuts for the jack-screws C. Each of these screws has a sprocket wheel D mounted on it over which passes continuously the sprocket chain E.

The upper ends of the screws C are pivoted in the boxes G attached to the frame F which supports the dynamo. One of the jackscrews, it will be noted, carries a worm wheel H which can be driven by the worm and

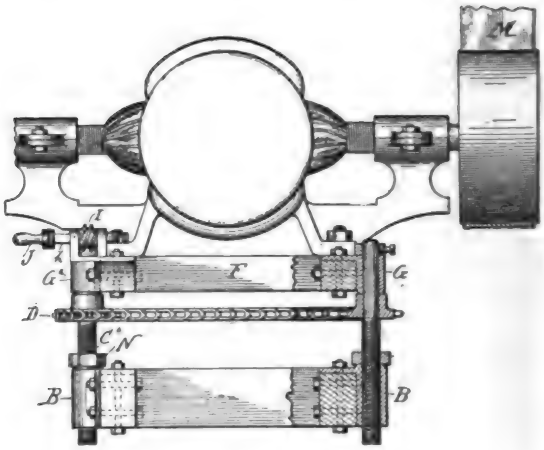

FIG. 2.—WRIGLEY'S VERTICALLY-ADJUSTABLE DYNAMO SUPPORT.

crank, and which turns all the screws simultaneously through the medium of the sprocket chain.

The effect of this is that by turning the crank the machine is raised or lowered uniformly and horizontal to the desired degree so as to bring the belt to full tension,

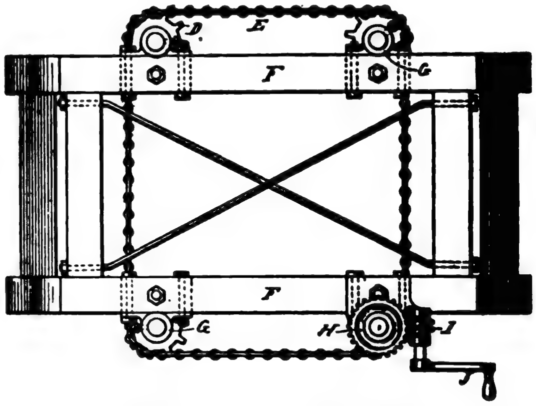

FIG. 3.—WRIGLEY'S VERTICALLY-ADJUSTABLE DYNAMO SUPPORT.

or to release it. When the machine has been raised so as to tighten the belt, the jam nuts N on the jackscrews are screwed up, so that no slacking can take place.

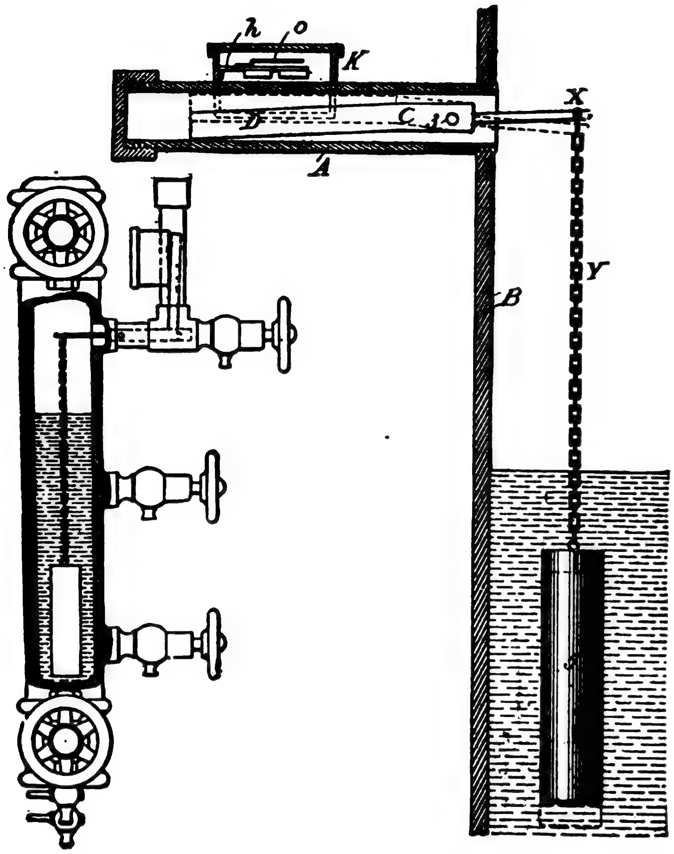
PROMISES OF CHEAPER ALUMINUM.

For some time the Cowles Electric Smelting and Aluminum Company, of Lockport, has been preparing to produce aluminum by a new process, which is claimed to be a successful solution of the problem of the cheap extraction of this metal from common clay. Eugene H. Cowles, president of the aluminum company, says: "We now expect to offer a pure metal made by a new process that is radically different from anything yet known to metallurgists—a process that is ridiculously simple in operation and almost theoretically perfect. By reason of two chemical discoveries it is found that the pure metal can be extracted direct from the clay. This can be done without the use of electrical heat. When operated on as large a scale as that on which iron is produced aluminum will be produced at a cost permitting it to sell at $200 per ton, a price less than the present price of copper. Alterations will be made immediately in our works here to make the metal on a large scale. Capitalists in New York are preparing to build immense new works of probably twenty times the capacity of the Lockport works. One of the large plants will undoubtedly be at Niagara Falls, where 10,000 to 12,000 h. p. will be required to operate it.

"As soon as the plant at Niagara Falls is in operation—say by July, 1892—the world can expect a supply of aluminum at least 99 per cent. fine, at prices not to exceed 50 cents per pound."

GHEGAN'S MAGNETO-ELECTRIC LOW WATER ALARM.

WHILE no apparatus can be expected to make entirely unnecessary the presence of an attendant for a steam boiler, a number of useful safety appliances can be employed to advantage. Among these, an audible, low-water alarm, especially when connected with the office of the superintendent, will go far towards securing immunity from accidents, and, at the same time, economy in operation.



FIGS. 1 AND 4.—GHEGAN'S MAGNETO-ELECTRIC WATER ALARM.

With this object in view, Mr. J. J. Ghegan, of Newark, N. J., some time ago brought out a simple device which has lately been considerably improved, so that it meets completely the conditions imposed.

The mechanical principle involved in this apparatus depends for its action on the simple fact that a body, when surrounded by a liquid, weighs so much less by the quantity of liquid displaced.

This principle is applied in making a normally submerged float actuate a circuit-closing device of novel construction. The accompanying engraving, Fig. 1, illustrates the mechanical arrangement and one method of attaching the alarm to a steam boiler. It consists of a short brass pipe, A, closed at one end, and containing a pivoted iron bar, D. The lighter end of the bar has a projection, X, extending outward through the open end of the tube.

This tube is screwed horizontally into a water column, boiler or tank anywhere above the highest water line, so that the projection of the lighter end of the pivoted bar is so placed that the movement of a body suspended therefrom to the water line is unobstructed. This suspended body has such a weight in proportion to that of the heavier end of the bar that the latter will outweigh, or be outweighed by, it, according to whether the body is submerged or not. Therefore, the heavier end of the pivoted bar will be moved between the upper and lower sides of the tube as the alternate rise and fall of the water submerges and uncovers the body suspended from its lighter end.

This movement of the pivoted bar could be made to open and close an electric circuit by direct contact, but in order to do this the contact points would have to be placed within the tube, which would expose them to dampness and corrosion, and consequent leakage of current and liability to failure as well as difficulty in their examination and adjustment.

These obstacles are entirely overcome by placing the contacts outside the tube in a tightly closed box, K, where neither steam, water nor dust can touch them, and the box can be opened for examination at any time.

The box, which is shown enlarged in Figs. 2 and 3, contains a pivoted permanent magnet, N S, with its poles near that part of the tube against which the pivoted bar, D, strikes in its upward or downward movement.

When the iron rod within the tube approaches the magnet poles they are attracted thereby and move towards it, and when the iron rod recedes they are drawn back to their normal position by a counter attraction, whose power over them the iron rod within the tube overcomes when in a favorable position.

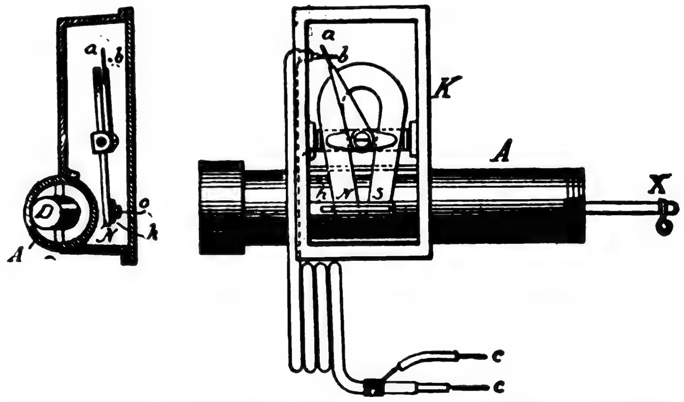
In this manner the motion of the bar within the tube is communicated to the magnet. The motion of the latter towards the tube is stopped by an electric contact, and it is thus made to control an electric circuit, containing an alarm bell.

Thus, when the float is submerged or surrounded by water, the parts occupy the positions shown, but when the water goes down and uncovers it, the movable parts take the positions indicated by the dotted lines in Fig. 1.

In this latter position it will be noticed that the iron rod D, is close to the magnet poles N S, which are thereby attracted and moved towards the tube, bringing the points *a b*, together, thus closing the electric circuit and putting the alarm in operation.

When the water rises and again submerges the float, the reverse operation takes place, and the parts resume their normal positions—the magnet being drawn away from the tube, and against the non-magnetic back stop.

It is evident that the alarm can be applied in a variety of ways to a boiler. Thus, it may be attached directly to the water column, as shown in Fig. 4, which allows of its being tested frequently and with ease. The alarm, we may add, is manufactured by the Ghegan Magneto-Electric Water Alarm Co., of Newark, N. J., and has been fitted to quite a large number of boilers, among them being three in Mr. Edison's laboratory at Orange, N. J.



FIGS. 2 AND 3.—GHEGAN'S MAGNETO-ELECTRIC WATER ALARM.

A PAN-ELECTRIC BILL OF COMPLAINT DISMISSED.

The bill of complaint of J. H. Rogers against ex-Attorney-General Garland and others, involving the ownership of Pan-Electric Telephone and Telegraph stock, was dismissed in the Court of General Term, at Washington, on November 26.

In experimental researches we may learn oftentimes more from our blunders than from our successes.—George M. Beard.

ELECTRIC RAILWAY STEAM ENGINEERING.

IT has been remarked on more than one occasion that the profit or loss in operating an electric light station lies in the management and utilization of the coal pile. This, of course, includes not merely the manipulation of the boilers, but embraces the entire steam plant, not forgetting the engines. Early in the history of electric lighting, when arc lights constituted practically the main system of electric distribution, the nature of the load was to a great extent a steady one, a certain number of lamps being operated on a circuit for a definite time, and then the entire circuit was shut down. This, of course, gave the engine a steady load and permitted of its being worked as a rule to its full rated capacity, with consequent economy. When the distribution of incandescent electric light currents became an established industry, it did not take long to determine the fact that the load had a definite relation to the time of day, and that it varied in such a manner that economy of operation required special arrangements of the engine service. This led to the equipment of stations with what are now known as "units of power." The size of the individual units, of course, varies with the magnitude of the station, the smallest unit being practically equal to the smallest load on the station. But another form of power distribution has sprung up since this question was a mooted one, involving a variety of conditions, the solution of which is of the greatest importance, not only as affecting the economy of operation so far as consumption of coal is concerned, but also as affecting the very life of the steam engine. We refer to the work of steam engines employed in driving dynamos for the operation of street railways. The results of past practice show that the nature of the fluctuations which are here met with can be compared to only one other case, namely, that of the rolling mill engine, in which fluctuations from no load to maximum, and vice versa, take place frequently within a few seconds.

Granted, that an engine can be built which will regulate its speed to take care of the fluctuation in load, will the strains that such service puts upon it allow of its operation without frequent repairs and a comparatively short life? In considering these two factors, the conviction is forced upon us that some radical change in the method of operating the generating plant of electric railways must be forthcoming, and, as a possible solution of the problem, we desire to draw attention to the plan proposed by Mr. C. O. Mailloux, which he details at length in this issue. The ease with which accumulators can be added to electric light plants to assist in taking care of a temporary overload and for equalization of the pressure is sufficiently well known, and the plan has proved so successful in practice that the application of the storage battery to railroad purposes is but a natural step. By the use of a small auxiliary machine and a set of storage batteries, even of the very lowest storage capacity, Mr. Mailloux shows that fluctuations in load exceeding by 100 per cent. the capacity of the main engine can be readily taken care of and involve merely an increase of 10 per cent. in the normal power delivered by the main engine. The system also assures the maintenance of the proper pressure on the line, or, indeed, if desired, may be made to act similarly to an over-compounded dynamo so that the potential on the line may be actually increased with increased load, thus more than compensating for the drop on the line with the heavier currents. As the storage capacity of the battery need be only very small, the ordinary Planté type of cell with thick plates, and whose life is practically indefinite, may, it is suggested, be used. The plan outlined by Mr. Mailloux is evidently so simple that we earnestly hope it will be given a trial by some of the electric railway companies, as there can be little doubt of its success when practically applied.

CHEAP POSTAL TELEGRAPHY.

POSTMASTER-GENERAL WANAMAKER in his annual report touches again upon the question of postal telegraphs. He has been given credit for entertaining some very definite ideas on this subject, but he does not offer any specific plan or scheme this time. He says that the "public imperatively demands cheaper telegraphy," but if that be so, we have rarely heard the imperative demands of a sovereign people made so meekly. Mr. Wanamaker contends that because the government here and in other countries controls the mail service, it ought to control the telegraph. "The general welfare will be similarly promoted by going one step further and giving the quickest of all modes of communication, namely, cheap telegraphic facilities, as it does mails, at points not profitable for private capital to reach, as well as at all other points." But as the government does not own the mail facilities and has to hire nearly everyone of them, including railway trains, stage coaches,

mail wagons, offices, etc., the only control of the telegraphs thus warranted would be that involved in a business contract; and there is no evidence that the Western Union Telegraph Company, or any other, would not be ready to make a contract to do such business at living rates. But no company ought to be expected to do that class of business at a loss. In the case of mail matter, the government does not inflict on the stage coach proprietor the loss that may be incurred in carrying it, but, on the contrary, gives him a satisfactory contract and meets the loss itself, possibly out of profits on other classes or portions of correspondence. Mr. Wanamaker remarks that "the people who pay in postage rates the cost of the postal system have a right to the use of the postal plants as a means of reducing the cost of telegraphic correspondence, and for the instant transmission of postal money orders." But there is a far higher benefit than telegraphic correspondence, and that is the quick bringing together of people so that they do not need to correspond. This benefit may take the shape of telephonic intercourse and even of railway and steamship travel, so that Mr. Wanamaker might with more propriety ask that postoffice surpluses should be spent in the perfection of long distance telephony, and in the development of fleeter "ocean greyhounds."

MATTHIESSEN'S STANDARD.

The preliminary report of the Standard Wiring Table Committee submitted to the American Institute of Electrical Engineers will be read with much interest by all whose work involves the determination of the resistance and weight of conductors for electrical purposes. While the exact value of the "legal ohm" is still a matter of some uncertainty, and, as we have seen, has been subjected to various changes within a comparatively short time, a practical standard, even if not absolutely exact has a *raison d'être*, and the more so as in the case of the Matthiessen standard, it is expressed in terms, and given for the value, of the metal most commonly employed in electrical work. Although, as has often been shown, the modern perfected processes of copper reduction have resulted in the production of wires exceeding 100 per cent. of the Matthiessen standard, the Committee point out that the objection which this might give rise to is offset by the advantage that commercial wires will appear the better for being compared with the lower standard. With the standard of resistance thus fixed upon, it is to be hoped that the Committee will soon be able to hand in its complete report on the standard wiring table, than which no more important subject in that special direction can occupy the attention of the Institute.

Training for the Next Execution.

The newspapers have published many details during the past week as to the preparations for the next electrical execution at Sing Sing, to take place, presumably, this week. We are told that various improvements in the methods and devices have been made, and that, this time, within two minutes after he leaves his cell, the prisoner will have been killed by the current. In spite of the cocksureness that is felt, it has been deemed advisable, however, as before, to try the current on some innocent animal, and on this occasion a strong, healthy horse was sacrificed. Perhaps the opponents of vivisection will have their attention arrested by this peculiarity of electrical execution by and by, and interfere. Such experiments with apparatus properly installed, for ordinary work, are quite unnecessary, and there is no reason why they should be allowed when the object of the execution is to teach the value and sacredness of life. May be horses, dogs and cattle don't count.

Travelin Facilities in New York City.

The all season has found the accommodations of the Manhattan Elevated system more inadequate than ever to the wants of the community. It is true that the crushing and crowding have been denied, but these are things of whose existence one has unfortunately to judge for one's-self. Travel on the Elevated becomes daily less endurable, and the need for better facilities cannot much longer go unfilled. It is this knowledge that has caused the press to give so much space to the new electrical underground road in London. The many features of advantage of electricity for locomotion when presented thus concretely are quickly grasped, and there has naturally been expressed a wish to see something of the same kind in New York. The fact is this city wants a reproduction of the London underground system, minus its steam locomotives, and unless such a road is built there will be no comfort in travel at all. With electric lights, electric motors and electric ventilators, an underground road in this city would be a great boon, relieving the streets of noise and gloom and dirt and enabling passengers to go quickly from one end of the Island to the other.

Electric Car Gear.

The numerous methods designed in the past and described in our columns might make it appear to be difficult to devise new ones for connecting the armature of the street car motor to the axle, but the variety and scope open to the inventor are such that new devices are brought out every week. A most ingenious one of its kind is that which we describe on another page, due to Mr. Mark W. Dewey. Utilizing the principle of the Arago disc, Mr. Dewey employs the electro-dynamic interaction between a magnet and a conductor in its neighborhood to transfer motion from the armature to the car axle. Of course the question of efficiency of transmission must naturally enter into the problem and upon this point it would be interesting to learn of the results of experiments.

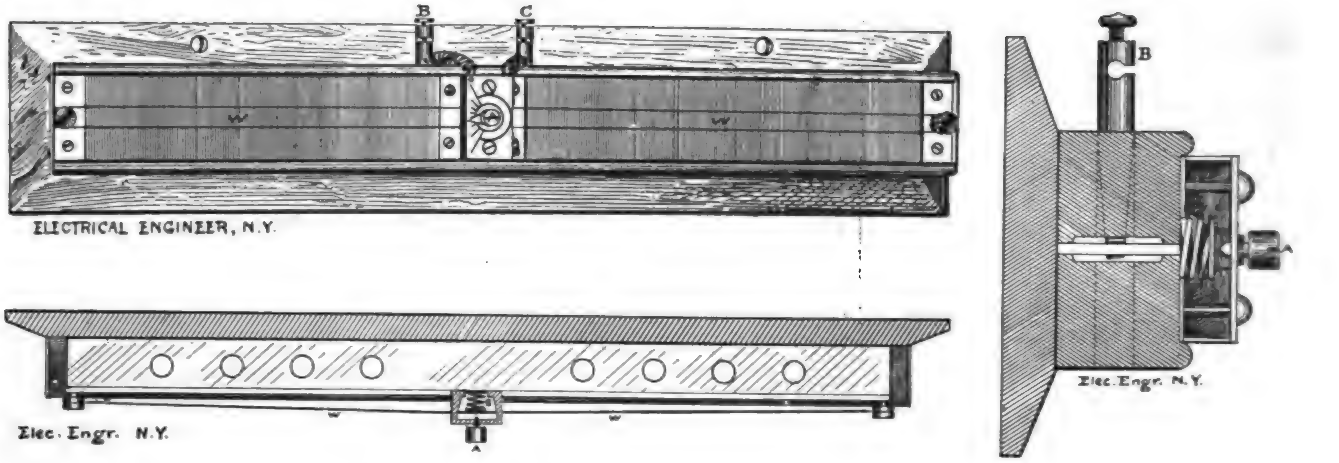
The Electrical Corps.

The suggestion put forward by Lieut. Bradley A. Fiske for the establishment of an electrical corps as an adjunct to the State National Guard, to assist in naval and military operations in time of war, has begun to attract notice. In his report to Congress, Secretary Tracy calls attention to the plan, and his language is that of approval. The corps would be, he says, especially valuable in wartime in fitting out new ships with electrical apparatus and in taking charge of plant on board ships in commission. In a recent letter to one of the editors of The Electrical Engineer, Secy. of War Proctor suggests, however, that the matter is one upon which the State authorities would have to act, and that it is doubtful whether the "arms and equipments" issued by the general government could include electrical apparatus.

PETIT & BRESSON'S FIRE ALARM THERMOSTAT.

The phenomenon of the expansion of solids and liquids by heat has been applied in a variety of ways to the construction of thermostats for the purpose of closing an electric contact following upon a definite rise in temperature. This method evidently permits in a very simple manner of detecting at once the starting of a fire and of giving the alarm electrically. Evidently the desired qualities in a thermostat are sensitiveness to rise in temperature and certainty of action. On the other hand, however, much annoyance has been caused by supersensitiveness in such apparatus, in virtue of which their contacts are closed by the vibration or jar in buildings so that an alarm is sent in when no fire exists. This has on more than one occasion given rise to carelessness in the attendants, who, being deceived a number of times, have, in a critical moment, been slow to act and hence caused considerable loss.

It was with the object of affording a sensitive thermostat, which at the same time should not be affected by jarring or other extraneous causes, that Messrs. Petit and Bresson, of Vittoria, Spain, have designed the apparatus illustrated in the accompanying engravings. As will be seen, the instrument, which is shown in perspective in Fig. 1, and in longitudinal and transverse section in Figs. 2 and 3, consists of a pair of looped wires w w which are kept taut by a spring s, the wires passing over a cover plate. The spring, with the plate, is in contact with one of the binding posts B. Passing through the cover of the spring is a screw A which is normally out of contact with the plate covering the spring, and which is connected to the other binding post C. Any increase in the temperature, of course, expands the wire w, which is pushed forward by the spring s and makes contact with the screw A opposite it. This closes the circuit and sends in the alarm.



Figs. 1, 2 and 3.—Petit and Bresson's Fire Alarm Thermostat.

It will be evident that the instrument can be made to send in the alarm at any desired elevation in temperature by properly regulating the distance of the screw A from the plate covering the spring over which the wires pass. The screw, it will be noticed, carries a pointer passing over the graduated circle upon which are marked the degrees in rise of temperature at which the alarm can be set. In this way the instrument can be used for a variety of purposes, not only for indicating the breaking out of fire, but also in dry-houses, and the like, where the temperature has to be kept at a certain definite limit The apparatus is very simple and has already been extensively applied in Spain in the Government bureaus and other public buildings.

The Highland Park Electric Light Company, Chicago, have adopted improved Candee wire for their primary circuits throughout their system, and have over 15 miles of it in use. They report that recently after three days of continuous rain a test showed that the insulation resistance of the primary circuits was over 1 megohm, notwithstanding the fact that the wire are built through alleys and in a great many cases hang through trees.

THE DISCHARGE OF ACCUMULATORS LEFT ON OPEN CIRCUIT.[1]

BY GASTON ROUX.

When it is not required to make use of a battery of accumulators during a certain period, what must one do to prevent them from being injuriously affected? That is a question which has often been put to me, and to which I have always replied: "Charge the battery to 'saturation,' and leave it to itself." I am aware that this is not the opinion of everyone, and that some recommend that accumulators should be charged to "saturation," and the liquid then emptied out, while others advise substituting pure water for the ordinary solution, and others still the substitution of concentrated acid for the ordinary solution. My opinion was based upon an experiment which I carry out each year at the Ecole de Physique et Chimie Industrielles de la Ville de Paris during the summer holidays. The experiment was repeated as usual this year, and I determined the exact amount of charge lost by the accumulators left on open circuit. The tests were made on two storage cells of the Julien type, having a capacity of 200 ampere hours, which were separated from the remainder of the battery. These accumulators are provided with paraffin spray arresters. The cells are of glass, and are contained in wooden boxes filled with sawdust, and supported on oil insulators. The cells, therefore, are thoroughly well insulated. The solution has a density of 1.2, when the cells are fully charged, and contains 6 per cent. by volume of saturated sulphate of soda.

The two cells were charged to saturation on August 5th, discharged on August 6th, and recharged on the 7th of the same month. I then left them to themselves until October 20th, that is to say, for two months and 13 days, when they were discharged. The discharge was stopped both on August 6th and October 20th, when the E. M. F. had fallen to 1.8 volts per cell. The quantity of electricity was found to be 233 ampere hours on August 6th, and 220 ampere hours on October 20th. Assuming that in each charge the accumulators stored the same quantity of electricity, we may conclude that the accumulators only lost on open circuit 13 ampere hours, or 6 per cent. of their charge during two and-a-half months. This result seems to me to prove that accumulators well made, well charged, and well insulated, are not injured by being left on open circuit. It also shows the good quality of these particular cells, and proves again that there is no local action between the active material and the antimony alloy supports. I should have liked to have carried out a similar test on accumulators with plain lead grids, but I had none at my disposal.

SOUNDINGS FOR THE NEW PACIFIC CABLE.

Information has just been received of the second season's work of her Majesty's war ship "Egeria," which has been detailed to make a systematic examination of the bed of the Pacific Ocean, with the object of discovering the best route for a cable from Canada to Australia. Last year was spent at Auckland, New-Zealand, and the Fiji group. The deepest sounding obtained south of the equator was 4,530 fathoms. Unfortunately, the nature of the bottom at this great depth was lost through the wire parting when heaving in. Three islands of the Phœnix group were surveyed in sufficient details to ascertain their suitability for a telegraph cable. The vessel is now further engaged with the survey of the work, and the British flag has been hoisted on all islands visited in the Pacific which are not under the protection of any other power.

THE CARPENTER-NEVENS ELECTRIC CAR HEATER.

We illustrate on this page a new electric car heater, now being introduced by Mr. C. B. Hanna, the general agent for the Carpenter-Nevens Electro Heating Co., of Minneapolis. We are indebted to the *Street Railway Gazette* for the illustrations.

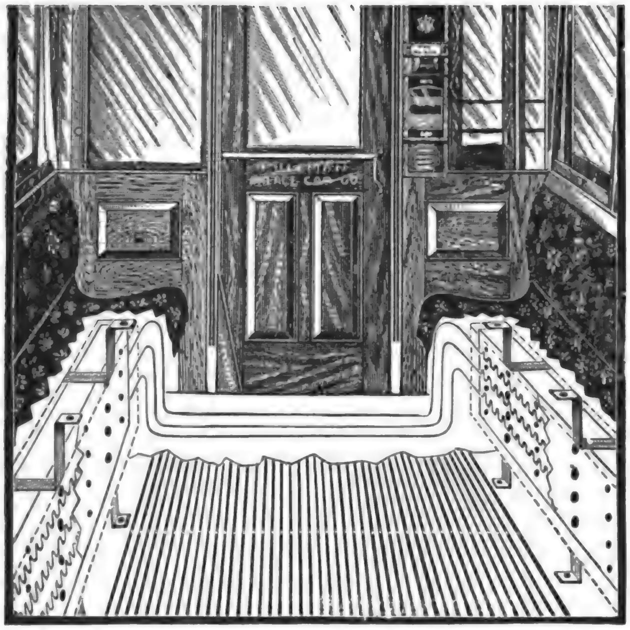

Fig. 2.—Carpenter-Nevens Electric Car Heater.

The heater, as shown in Fig. 1, consists of a narrow strip, or ribbon, of asbestos enclosed in sheet iron, about 3 in. in width and about ½ in. in thickness, which is intended to extend from one end of the car to the other, under the seats, on both sides, midway between the seat and the car flooring, and protected from the person or clothing of the passenger by a wire screen. It is enclosed on all sides except the face in a copper radiator or reflector in order to divert the heat into the proper channel and to protect against loss. A second strip of iron of the same dimensions is attached to the first strip by a single row of small bolts extending from end to end, thus serving the purpose of a compressing plate and, at the same time, forming the other side of the heater. The resistance wires are imbedded in asbestos, and the compression plates are bound firmly together by means of the small bolts before mentioned, and are located between the two strips of iron. Three or more resistances, of zigzag form, are used which not only extend from end to end of the heater, but are also connected with companion resistances in the other heater on the opposite side of the car, so that a single resistance extends not only down one side of the car in both heaters, but also around the car on both sides. In other words, it is intended that from two to three resistances, each one in parallel and independent of the other, extending from end to end of the heater, but each one connected in series with that of a companion on the opposite side of the car, shall be used, in order that, when the circuit is closed upon one of them a certain current will flow, which, of course, with the given number of volts, is inversely as the resistance. The heat resulting from the flow of the current through the resistance becomes equally distributed on both sides of the car from end to end, thus equalizing the amount of heat evolved. Since two or more resistances are then in the circuit, so, if three resistances are cut in the circuit, the amount of heat will be increased again over that of the other two, and if these resistances have the same number of ohms under all conditions, there will be three times as much current consumed and consequently, three times as much heat evolved as when only one resistance alone is used in the circuit. This provision is made in order that the heater may be adapted to any kind of climatic or atmospheric conditions.

With regard to the amount of power required to generate the requisite amount of electricity for the development of the required temperature, it is claimed that 9 amperes of current at 500 volts, equal to about 6 to 7 h. p., are used at first, but only for a few minutes, after which but 1½ amperes are used.

The current is controlled by the motor-man.

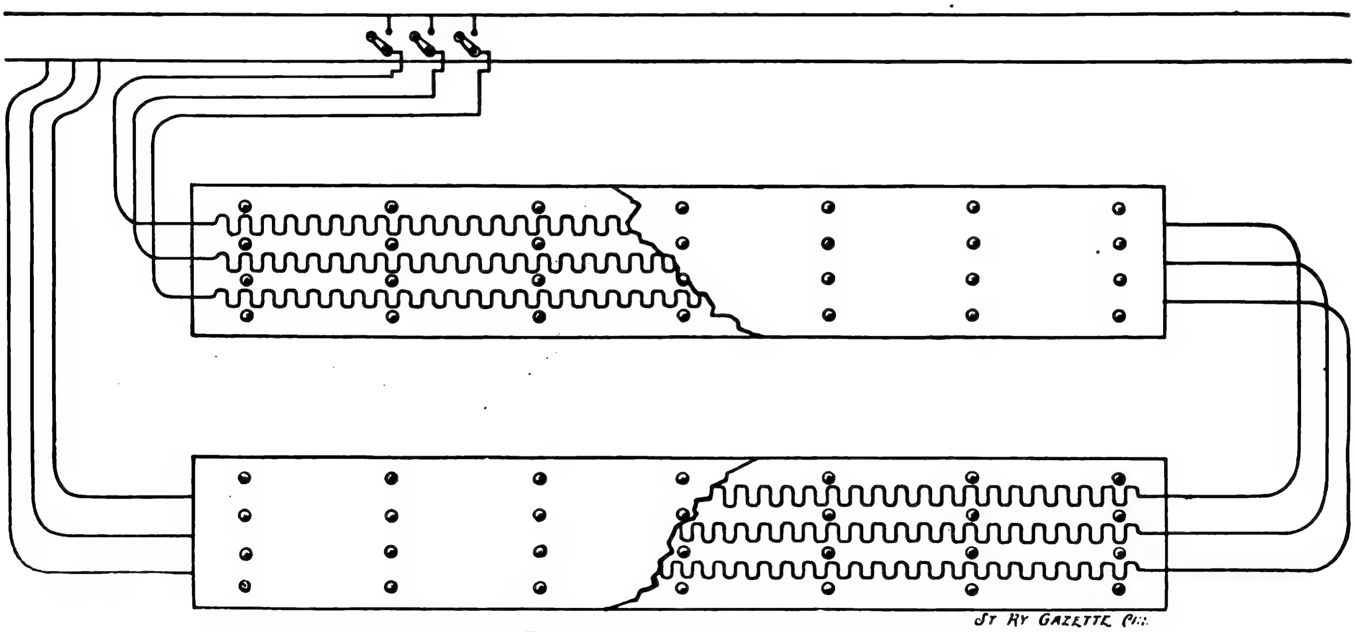

Fig. 1.—The Carpenter-Nevens Car Heater.

Fig. 2 shows the heater as placed on the Pullman street car—a section of the seat having been removed in order to afford a view of the heater in position.

A PROPOSED CABLE TO FLORIDA.

An English company has submitted a proposal to lay a cable from Nassau to the Florida coast in consideration of an annual subsidy from the colony. Details of the project are not yet made public. It is thought that the Legislature, which is to meet in extra session, will accept the proposition.

VAN DEPOELE'S ELECTRIC RAILWAY BRAKE.

MR. C. J. VAN DEPOELE, not content with his many inventions in electric traction, has been giving attention to electric railway brakes. One of his recent inventions is shown in the accompanying engraving. Mr. Van Depoele deems previous devices to be for the most part wasteful of electric energy, inasmuch as they have frequently depended upon the employment of artificial resistances as means for controlling the currents actuating the brake mechanism, and seeks to make a more efficient apparatus by employing the counter-electromotive force from a subsidiary motor.

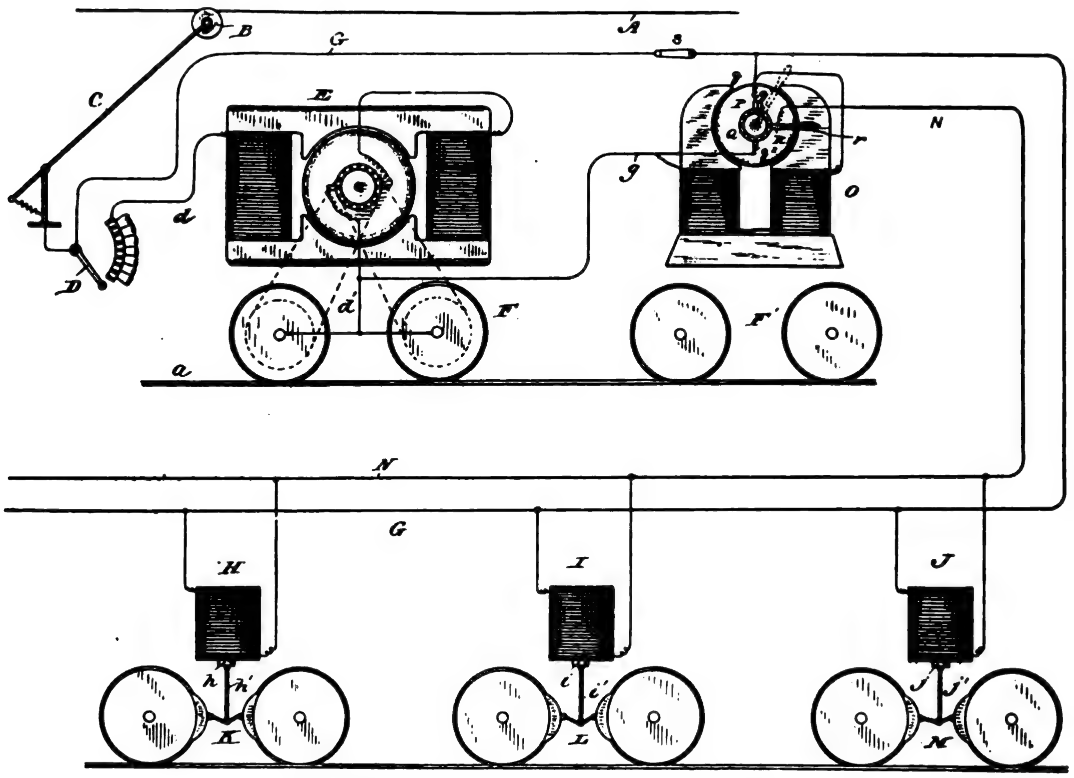
This method is said to secure the most delicate adjustment and control, and includes no dead resistances which would be liable to become overheated, or destroyed by the continuous use frequently required of brake apparatus.

The apparatus is illustrated in connection with a number of electric-railway vehicles.

A represents the supply-conductor of an electric railway, B a contact device from which current is carried down the trolley-pole C to a switch D, through which it may pass by which the car or train is controlled, in position to be easily reached by the motor-man.

The motor O is provided with the usual sectional commutator Q, which is provided with main positive and negative brushes q' q^2, and also with a third commutator-contact in the form of a movable brush R, supported upon a hand-lever r, mounted concentric with the armature-shaft q. The positive commutator-brush q' is connected to and receives current from the branch conductor G. The opposite main brush q^2 is connected with the return-circuit of the system represented by the grounded conductor d'. The field-magnet circuit of the motor O is connected to the main commutator-brushes in derivation, the motor being operated at constant speed.

All current passing through the solenoids must flow through the conductor G, returning by way of the conductor N and movable brush R. Consequently the position of R with respect to the main brushes of the motor O will determine the amount of current which can flow through the circuit G N. When the movable brush R is opposite to the main brush q', no current whatever will flow in the circuit G N. As soon, however, as the movable brush is



VAN DEPOELE'S ELECTRIC RAILWAY BRAKE.

conductor d to the coil of a motor E for propelling a motor-car, the car being indicated by the wheels F F'. One side of the circuit is represented by the conductor A and the other by the rails a of the track. The circuit of the motor E is connected to the track through conductor d'. From the switch D extends a branch conductor G, which traverses the working-circuit shown as a train to be electrically braked.

A number of sets of brake mechanism K L M are shown, represented by solenoids H I J, each provided with an iron plunger h i j, mechanically connected with the brake mechanism by connecting-rods h' i' j'. One terminal of the brake-actuating solenoids is connected with the conductor G, the other terminals being connected to a second conductor N, the solenoids being therefore in multiple-arc relation to each other and to their supply-circuit. The subsidiary motor O, whose counter-electromotive force actuates the brakes, is, for convenience, located upon the motor-car or at or near the point from moved away from the brush q' current will begin to flow in the working-circuit, the electromotive force increasing continually until the moving brush is in position alongside the other stationary brush q^2, when the current will flow through the circuit G N and traverse the solenoids H I J to the full extent of their capacity. Thus, by moving the brush R between the stationary brushes q' q^2 the current in the brake or other working circuit can be regulated with great precision, eliminating wasteful resistance, as well as delicate parts. The motor O may be a quite small one, its size depending upon the extent and capacity of the working circuit. It is obvious that the armature of the motor need only be in motion during such time as the brake is in use, although it may be found desirable to keep it constantly in motion in order to be prepared for emergencies. A switch s is provided in the conductor G for opening the brake-circuit when desired.

It will be seen that Mr. Van Depoele's invention is not limited to employment upon electrically propelled cars, but

may be used on steam or other railways, if a suitable electric generator be provided for operating the brake-setting device. It is also clear that no particular form of brake-mechanism is requisite, but that many varieties might be used.

PRELIMINARY REPORT OF THE STANDARD WIRING TABLE COMMITTEE,[1]

IN REGARD TO MATTHIESSEN'S STANDARD OF RESISTANCE OF COPPER.

The Council of this Institute at its regular monthly meeting held December 3rd, 1889, appointed a committee "to formulate and submit for approval a standard wiring table for lighting and power purposes."

The committee appointed consists of the following members of the Institute: Thomas P. Conant, Dr. Louis Duncan, Prof. Wm. E. Geyer, A. E. Kennelly, George B. Prescott, Jr., E. Wilbur Rice, Jr., Prof. E. P. Roberts, Prof. Harris J. Ryan, William Stanley, Jr., Dr. Schuyler S. Wheeler, and Francis B. Crocker, chairman. This action was taken by the council with the object of overcoming or reducing the great confusion which now exists in regard to the standards and constants of electric conductors.

At the first meeting of the committee held January 10th, 1890, it was decided to confine the work at first to the three subjects of Standard of Resistance, Temperature Coefficient, and Safe Carrying Capacity of Copper, since these are of fundamental importance.

The subject of Matthiessen's Standard alone is so confused and involved, and the discrepancies are so great between the best authorities, that the committee has devoted its attention almost entirely to this subject up to the present time.

After a very thorough investigation of Matthiessen's work with a view to ascertaining what his standard really was, by a sub-committee, consisting of Prof. Wm. E. Geyer, Mr. George B. Prescott, Jr., and the chairman, the conclusion has been reached that Matthiessen's "Mile Standard" (one statute mile of pure copper wire 1-16 inch. in diameter has a resistance of 13.59 B. A. units at 15.5° C.) is not the true one although very commonly used. We consider the correct Matthiessen's Standard and the one in which he, himself, had most confidence was the "metre-gramme" standard (resistance of pure hard-drawn copper wire, one metre long weighing one gramme = .1469 B. A. unit at 0° C.). This has the disadvantage that it is expressed in terms of weight instead of diameter. It is, however, very much more difficult to get the exact mean diameter of a wire than to get its exact weight, as Matthiessen himself states. Furthermore, by selecting the most reliable constants given by Matthiessen and corroborated by investigation and correspondence with the best authorities, we have by calculation converted this "metre-gramme" standard into a standard referred to dimensions and independent of weight, which is the form generally used.

The various constants selected, the method of calculation, and the values deduced are given in a table at the end of this report.

As to the fact that wires may be found which test 102 per cent. of Matthiessen's standard or even higher, we are of the opinion that this is no real objection provided the value of the standard is definite and generally accepted. A standard which is not the highest attainable value may even be considered an advantage since the average commercial wires will approximate to it more closely.

Although we believe the standard we recommend will answer the purpose temporarily and probably permanently, nevertheless we think that if a thoroughly correct and complete redetermination of the standard resistance of copper could be accomplished, it would be a benefit to electrical science and industry. Favorable offers in this direction have already been received by this committee from Johns Hopkins University, Cornell University and Columbia College, and it is very likely that this redetermination may be undertaken.

This committee purposes next to take up the subject of the safe carrying capacity of wires.

Matthiessen's standard recommended by this committee is:

A hard-drawn copper wire 1 metre long weighing 1 gramme ("metre-gramme") having resistance of .1469 B. A. unit at temperature of 0° centigrade.[2]

From this standard we calculate by taking the value 8.89 for the specific gravity of copper, that a hard-drawn wire 1 metre long and 1 millimetre in diametre ("metre-millimetre") has a resistance of .02104 B. A. unit at 0° C. This value is also given by Matthiessen.[3]

Matthiessen's figures[4] for relative conducting power are:

Silver	100
Hard or unannealed copper	99.95
Soft or annealed copper	102.21

From these the resistance of hard copper is found to be 1.0226 times that of soft copper; therefore the resistance of a soft copper wire 1 metre long and 1 millimetre diameter is .02057 B. A. unit at 0° C.

From this the resistance of 1 cubic centimetre of soft copper is found to be .000001616 B. A. unit at 0° C.

And the resistance of soft copper wire 1 foot long and .001 inch in diameter (mil-foot) is 9.720 B. A. units at 0° C.

Taking one B. A. unit as .9889 legal ohm, any of the above values may be converted into legal ohms. To find the conductivity of copper at temperatures other than 0° C., Matthiessen's formula may be used $C_t = C_0 (1 - .00387\,t + .000009009\,t^2)$.

Table of values based upon Matthiessen's correct standard.

	B. A. Units. 0° C.	Legal Ohms. 0° C.
Matthiessen's Standard metre gramme hard	.1460	.1453
Metre-gramme soft	.1436	.1420
Metre-millimetre hard	.02104	.02080
" " soft	.02057	.02034
Cubic centimetre hard	.000001652	.000001634
" " soft	.000001616	.000001598
Mil-foot hard	9.940	9.829
" soft	9.9720	9.612

Specific resistance of hard copper (1 cub. cent.) = 1634 C. G. S. units.

Specific resistance of soft copper (1 cub. cent.) = 1598 C. G. S. units.

Matthiessen's standard specific gravity of hard copper, 8.89.

Resistance of hard copper is 1.0226 times that of soft copper.

Resistance of soft copper is .9779 times that of hard copper.

Legal ohm is equal to 1.0112 B. A. unit.

B. A. unit is equal to .9889 legal ohm.

F. B. Crocker, Chairman.

ELECTROLYSIS OF ANIMAL TISSUES.[1]

BY G. N. STEWART

A preliminary account of part of the work was given in the Proc. Roy. Soc. Edin., 1888, and a short description of later results at a meeting of the Physiological Society at Cambridge in March last. The full paper is being published in a volume of memoirs from the physiological laboratory of the Owens College, Manchester. The chief results are here summarized:

(1) The first part of the research was directed to answering two questions: (*a*) *Is the conduction in animal tissues entirely or chiefly electrolytic?* (*b*) *What are the electrolytes?* It is shown that by far the greatest part of the conduction at any rate is electrolytic, and that the best conductors by far are the inorganic constituents of the tissues. Next to these, but at a great distance, come some of the nitrogenous metabolites. The proteids are exceedingly bad conductors.

(2) *The changes produced in simple proteid solutions* were next investigated. It is shown that the proteids are affected not by primary electrolysis, but by the products of electrolysis of the salts.

The effects vary to some extent with the current density. In solutions of coagulable proteids alkali-albumin is formed at the cathode, and acid-albumin at the anode, some of the proteid being coagulated at the latter.

(3) *The effects of electrolysis on isolated tissues and on some of the liquids of the animal body.*

Striped Muscle.—Great changes were found in the microscopic appearance of the fibre. The nuclei became very prominent in those near the anode, with apparent coagulation of the sarcous substance, suggesting the action of a dilute acid. At the cathode the fibres were more homogeneous than before. The striation was impaired. Chemically, the same changes in the proteids were found as in simple proteid solutions, and a distinct effect on the distribution of the salts was made out, by estimating the ash in different parts of the muscle.

Blood.—Entire defibrinated blood, blood serum, and pure hæmoglobin solutions were used. There was no indication that hæmoglobin, or any derivative of it, acts the part of an ion. At the anode the reaction becomes acid, and acid-hæmatin is formed, which remains partly in solution and is partly thrown down, the solution becoming less deeply colored. When the current is strong or long continued the hæmatin suffers further change and is decolorized, apparently by the oxygen or chlorine set free. If a reducing agent is present at the anode, the hæmoglobin there is not affected by the electrolysis. At the cathode alkali-hæmatin is ultimately formed, although its less definite spectrum does not show itself so soon as that of acid-hæmatin at the anode. The proteids of the serum and corpuscles are partly coagulated at the positive pole. At the cathode they are partly changed into alkali-albumin.

1. *Nature.*

Bile and urine were taken as further examples of animal liquids.

(4) *The effect of electrolysis in the living body.*

Pithed frogs and anæsthetized rabbits were used. This part of the work is still incomplete.

THE MAGNETO-OPTICAL GENERATION OF ELECTRICITY.[1]

BY SAMUEL SHELDON, PH.D.

WHILE experimenting upon the effects of alternating currents of electricity upon the plane of polarized light, results were obtained which made it feasible to try a series of experiments, in which the Faraday arrangements were reversed. Although the series is incomplete, yet the little that has been accomplished seems worthy of publication.

It is well known[2] that if a beam of plane polarized light be passed through a tube containing bisulphide of carbon, and if the tube and beam lie in the direction of the lines of force of an electromagnet about to be excited, the plane of the emergent beam will be rotated upon exciting the magnet. The direction of rotation will be the same as that of the exciting current, and the amount of rotation will depend upon the strength of the current. If the current be reversed the plane will be rotated in an opposite direction and by exactly the same amount. Thus the rapidly alternating current would produce a rapid swinging to and fro of the plane of light.

Now, if a difference of potential, under these conditions, produces such a rotation of the plane, why should not a rapid rotation of the plane, under exactly the same conditions, produce an inverse difference of potential between the terminals of the coil? A continuous rotation should produce a continuous current of electricity and an oscillating of the plane an alternating current. The experiments which have been performed verify the latter supposition.

The coil employed was wound upon a thin brass tube as a core. This was closed at each end by plates of glass and was provided with holes for filling with carbon bisulphide. Its length was 175^{mm} and its diameter 23^{mm}. Upon this was wound the coil from double silk-covered copper wire of 0.85^{mm} diameter. When wound the length of the coil was 150^{mm} and its diameter 45^{mm}. The resistance was 7.21 ohms.

A quantitative measurement of the Faraday effect was first made and in the following manner: A beam of light from an incandescent lamp, after passing through a large nicol, was made to traverse the bisulphide of carbon in the coil. Upon emerging the beam was brought to extinction by the proper adjustment of an analyzing nicol. A measured current of electricity was now passed around the coil. This necessitated a readjustment and rotation of the analyzing nicol to reproduce extinction of the beam. Within the limits tried this rotation was proportional to the current strength. As a mean of many measurements it was found that a current of 1 ampere required a rotation of 78 minutes of the analyzer. Accordingly 278 amperes would be required to rotate the plane through 360°, providing the proportionality between current strength and rotation remained unaltered.

Now, if we consider a plane polarized ray of light to be made up of two opposite circularly polarized rays, then a particle of ether in the bisulphide of carbon describes a simple harmonic oscillation in a plane. This motion in a straight line is the resultant of the two oppositely directed, equiperiodic, circular rotations of equal amplitude. If now a magnetic field be created, the particle undergoes an instantaneous circular electric displacement which results in the retardation of one and the acceleration of the other component rotation. The line of oscillation suffers rotation as a result, and assumes a new position. The displacement must be instantaneous, for, were it continuous, the line of oscillation would continue to rotate and the analyzer could not be made to produce extinction. If now, instead of allowing the magnetic field to produce this circular displacement, we superimpose, by mechanical means, a third rotation upon the two existing components, then a magnetic field should result and an electromotive force be induced in a coil surrounding that field. Such a result would be obtained by rotating the polarizing nicol. The rapidity of rotation must be very great, and, if it requires 278 amperes (an impressed electromotive force of 2,000 volts) to rotate the plane through 360°, then to produce this electromotive force the polarizer must be revolved with a frequency of the same order as of the oscillations of light. But a nicol cannot be revolved much above 200 times per second. The centrifugal force resulting from a higher rate will, owing to the strain produced, interfere with the performance of its functions as a polarizer. This rate of 200 revolutions per second would produce, in the apparatus employed, an electromotive force of perhaps 0.000000001 volt, giving a current too small to be detected by any galvanometer in my laboratory. Hence use was made of the extreme delicacy of the telephone as a substitute, and a swinging of the plane instead of a revolution.

The arrangement of apparatus was as follows: Light from an arc lamp, after passing through a large nicol, was reflected, at a very obtuse angle, from a small movable mirror and then passed through the bisulphide of carbon in the coil before mentioned. The two terminals of the coil were carried to a room three stories below and in another part of the building. Here they were connected through a telephone and a switch. The mirror (10×30^{mm}) was fixed in a brass frame free to rotate about an axis nearly parallel with the ray of light. This frame was connected by an eccentric and gears to the main shaft in the work shop. By this arrangement the mirror was made to oscillate through 45° about 300 times each second. The plane of polarization was thus twisted through twice that amount, or 90°, in the same time. While this oscillation was going on in the workshop, an ear placed at the telephone at the other end of the circuit could easily distinguish a tone, which, however, was the octave above that made by the moving mirror. When the circuit was broken the sound ceased to be heard, but upon again closing the tone became audible. With a rate of 200 oscillations per second the note was not so easily distinguished. But upon closing the circuit that peculiar sizzling noise so common in telephone circuits was heard.

During the experiments the mirror was frequently broken by the high rate of vibration. But another was quickly substituted by my assistant, Mr. Baker, whom I have to thank for this and the construction and management of the rotating apparatus.

REPORT OF THE B. A. COMMITTEE ON ELECTRICAL STANDARDS.[1]

THE first paper was by Mr. Glazebrook himself, "Variation in Some Standard Resistance Coils." The repeated careful comparisons show an excellent constancy of five of the eight coils; there are very slight deviations, for which a temperature error of ¼ degree would account. But the coil F, which, like the coils G and H, consists of a platinum silver alloy, has not recovered its character; it has long been distrusted and now shows a gain in resistance of .0007 B. A. unit, a deviation, it will be granted, noteworthy only in the case of a standard coil. As the insulation resistance is perfect, Mr. Glazebrook ascribes the error to a contraction of the paraffin, the coil being probably mechanically damaged in handling. The other two platinum-silver coils have also lost .0002 and .0001 B. A. unit respectively; and some speakers did not trust the alloy. Professor Perry has twisted flat strips of one wire of this alloy, and found them anything but equal in behavior; and Mr. Glazebrook will be glad to have any such coils back for re-examination. The new coils are wound without solid paraffin to avoid any chance of mechanical damage.

The second paper by Messrs. Glazebrook and Muirhead, "Some Standard Air Condensers," reported the completion of two air condensers after Muirhead's pattern. They consist of 24 concentric brass tubes, $\frac{1}{16}$ inch thick; outside diameter, 1 foot; height, 3 feet; leaving ¼ inch air space between tube and tube, connected to two parts of twelve alternate tubes. The joint pieces are also brass, the insulation ebonite. The condensers have a capacity of .02 microfarad each, and have been tested by Maxwell's method in August and December last year, and May and June this year. The one condenser proved excellent and loses about one-thousandth of its charge per minute; the other seems a little faulty. The fourth paper "Comparison of a Platinum Thermometer with Some Mercury Thermometers," gave further details and curves respecting this most delicate thermometer of Mr. R. H. Griffiths; the Kew thermometer is still always $\frac{1}{100}$ degree lower.

Mr. Fitzpatrick contributed the third paper "On the Specific Resistance of Copper." The wires tested were about 1 metre long, and weighed 1 gramme, and the bridge arrangement adopted determined the length of that wire of one-thirtieth ohm resistance. The specimens were supplied by Messrs. Sutton and other manufacturers, and by Mr. Fitzpatrick himself, who electrolyzed carefully purified copper sulphate. His and Sutton's pure copper gave the resistance of Matthiessen, 1767×10^{-9} B. A. unit at 18 degrees; the specific gravity of this copper was 8.9. Other copper wires of specific gravity 8.940 and 8.946, understood to be Elmore's, had resistances still lower by 2 and 2.4 per cent., the respective figures being 1731 and 1724; the greater conductivity was due probably not to greater purity, but to the greater density. The report recommended the adoption, as a standard of resistance sufficiently near the absolute ohm for practical purposes, the resistance of a mercury column of 1 square millimetre section and 106.3 centimetres length; this would give .98656 or in round figures .9866 as the ratio of the B. A. unit to the ohm. This corresponds to .9535 B. A. unit as specific resistance of mercury, and to a mercury column of 104.87 centimetres length as representing the resistance of the B. A. unit.

Twenty-eight towns in the departments of France have now obtained telephone service. In eight other towns the telephone lines are in construction and will be completed in two months' time. Other towns will shortly be added. There are only two towns possessing telephones in Algeria, viz., Algiers and Oran.

1. Presented at the British Association Meeting, Leeds.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.

Anonymous communications cannot be noticed.

The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.

In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.

Sketches and drawings for illustrations should be on separate pieces of paper.

All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

METHODS OF TESTING TRANSFORMERS.

[147.] I have read in your issue of Nov. 12, the discussion of Messrs. Tobey and Walbridge's paper on the Stanley alternating current dynamo. In the discussion Dr. Carey T. Hutchinson drew attention to the fact that experiments, similiar to those described in that paper, and also very much like Prof. Ryan's and Messrs. Humphrey and Powell's work on transformers, had been made at Johns Hopkins University several years ago, and that in spite of this no reference had been made by these gentlemen to the work of the previous investigators.

To quote Messrs. Powell & Humphrey's paper: "It is worthy of mention that this method which gives something so definite and fundamental in the treatment of alternating currents, has only come into use within the past year." The method referred to is spoken of as Prof. Ryan's method.

That the work on transformers done at Cornell is valuable is unquestioned, but the disposition manifested to claim as original, in 1890, a method which was not new in principle in 1887, is not to be commended If the method referred to be compared with that used by Messrs. Hutchinson, Wilkes and myself in 1887, and fully described in *The Electrical World* (March 31, 1888, et seq.,) it will be seen that they are practically identical, and the results of our work, which dealt with open and closed circuit transformers under various conditions, are closely the same as those given by the later investigators. LOUIS DUNCAN.

JOHNS HOPKINS UNIVERSITY,
BALTIMORE, Nov. 18.

THE EFFECT OF SHIFTING THE BRUSHES.

[148.]—Will you kindly decide for me in your next issue this mooted question: Why does the raising or lowering of dynamo brushes—changing their position on the commutator—increase or diminish the current both in arc and incandescent machines?

INQUISITIVE.

New York.

[The diminishing of the current is a secondary effect caused by the lowering of the difference of potential, when the brushes are shifted from their position of maximum effect. An admirable explanation of this subject will be found in Prof. Silvanus P. Thompson's "Dynamo Electric Machinery," 3d Edit., p. 64 et seq.—EDS. E. E.]

CHARGING STORAGE BATTERIES FROM ALTERNATORS.

[149.]—Will you please answer the following in your esteemed journal: What would be the result of using an alternating dynamo in combination with a storage battery?

R. C.

Annapolis, Md.

[Under the ordinary conditions, with the positive and negative impulses of the alternator of equal strength, the effect upon the storage battery would be nil. Several methods have, however, been devised so as to permit of the employment of alternating currents for the purpose described, in which the positive and negative impulses are differentiated with respect to the battery, so that impulses of only one sign act upon it. Mr. Tesla, among others, has invented and patented a number of such methods.—EDS. E. E.]

TELEPHONIC IMPROVEMENTS AT CINCINNATI.

Owing to the growth of the Walnut Hills district, the Cincinnati telephone people have found it necessary to make a change in the location of their branch offices, and the old Broadway exchange has now been removed to McMillan street, Walnut Hills. The work has been carried out under the active direction of Capt. G. N. Stone, the general manager of the company. A building has been constructed with a special view to exchange uses, and the operating room is on the second floor. It is finished in mahogany and is equipped with an improved multiple board, of the Western Electric Co.'s make. Besides the operating room, a sitting room is provided for the operators when on relief, and is comfortably furnished. The building has electric light and gas and steam heating. The cost of the whole is about $50,000, about half of which went for the new switchboard and its accessories. The change from the old office to the new was made in 26 seconds, 500 wires being switched.

EUROPEAN CORRESPONDENCE.

LONDON

The First Plant of the St. Pancras Vestry.—Report of the Metropolitan Electric Supply Co.

THE foundation stone of the Stanhope street station, the first of the St. Pancras vestry, has been laid. The plant will be capable of supplying low tension current to serve 10,000 incandescent lamps of 16 c. p. simultaneously, and at the same time high tension current will be provided on a separate set of mains to serve public lights in the streets, to the extent of 90 ten-ampere arc lights, or a larger number of lamps of equivalent candle-power at the outset.

There will be nine low tension, and two high tension dynamos, one of each sort serving as a standby or reserve. All the dynamos will be driven direct by triple expansion condensing engines. There will be six sets of batteries or accumulators (capable of serving 800 or 900 lights) to work all the lights in use at periods of minimum demand when the engines and dynamos would not be working and they will further act as an additional standby or reserve.

Provision is made at the outset for 5 miles of distributing mains which are designed to carry current for 25,000 incandescent lamps of 16 c. p. in use simultaneously, and separate mains are provided for the public street lighting.

The St. Pancras parish now remains intact in the hands of the vestry for the purpose of distributing electrical energy under a provisional order obtained in 1883. No company has as yet succeeded in obtaining powers within the area.

The report of the Metropolitan Electric Supply Co. states that while it is impossible until the accounts have been audited, to review the financial position in detail, the directors are of opinion that the prospects of the undertaking are such as to warrant them in looking forward to a satisfactory dividend being earned in the ensuing year. During the fourteen months which have elapsed since the company obtained Parliamentary powers upwards of forty miles of electric light mains have been laid in pipes under the streets of the principal thoroughfares of the company's districts. Current is at present supplied from four central stations.

LONDON, Nov. 8, 1890.

Electric Light in Chagford.—Underground Circuits in Berlin and Vienna.—Traction in France.—A Controversy at Leamington.—Electric Light in Belgium.—Electrical Trades Section and Overhead Wires.—Metropolitan Electric Supply Company.—Institution of Electrical Engineers.—The Channel Telephone.—Halifax and Bermuda Cable.—Central Stations in Germany.—Telephones in France.—Train Lighting in Hungary.

ANOTHER illustration of the spirit of progress shown in small villages comes from a place named Chagford. Here a millwright and machinist has taken an old mill which has been uninhabited for several years and intends to supply the inhabitants with electric light. Power will be obtained from a large water wheel. Dynamos are installed, and already current is being supplied.

The results obtained with the underground telephone circuits in Berlin have been so successful that the Imperial Post Office is making further experiments. Telephone cables are now laid between Berlin and Küstrin, and Berlin and Hamburg. I hear that experiments have been made in this direction by the Vienna Postal authorities.

The action taken about a year ago by the French Electrical Accumulator Co. of placing several accumulator cars on the Levallois and Madeleine line has been followed up by another company. Cars worked by storage batteries are to run between the Palais de l'Industrie and the Place de la Concorde.

A controversy likely to be carried on by the lawyers has arisen between Messrs. Chamberlain and Hookham, electrical engineers, and the Leamington Corporation. It is said that the light supplied by the firm is below the standard, and on those grounds payment is refused. On the other hand, the contractors consider the tests unfairly carried out. They will ask the Board of Trade for a provisional order enabling them to supply the whole of the borough with electric light. This is a most doubtful policy. Many of the companies here apply for powers, forgetting that before they are granted the consent of the local authorities must be obtained. Failing to gain the permission, they sacrifice half the deposited sum, which is by no means an inconsiderable amount.

The Belgian town of Ninone, situated about fifteen miles to the westward of Brussels, is the first town in that country to adopt the electric light. It is a curious fact that this place was the first to adopt gas. The concession granted to the gas company expired on the 30th of September last, and the municipality having decided to abandon gas, have entered into a contract with an electric light company of Brussels to supply light for thirty years. The lighting is to include streets, squares and public places, as well as private dwellings. The installation comprises

two large boilers, two Ridder engines of 20 h. p. each, two Siemens dynamos of 16,000 watts and two batteries of Tudor accumulators capable of feeding 600 lamps for six hours. The distribution is effected by means of overhead wires. The old gas lamp fixtures will be used. The cost will be rather less than that charged for gas.

A meeting of the members of the Electrical Trades Section of the London Chamber of Commerce took place on Monday. Mr. Crompton, in his capacity of chairman, spoke with considerable emphasis on the subject of the Board of Trade Rules relating to overhead wires. Two most important rules have been embodied, which, if persisted in, will preclude the possibility of the extension of electric lighting in town. The first of these rules says that every wire whatever its thickness shall have a rubber coating of the thickness of one-tenth of an inch, and on the top of this there shall be the usual braiding or tape. The Silvertown India Rubber Company state that the cost of a wire insulated in the prescribed manner would be £80. The cost of the wire which this same company guaranteed to be absolutely safe is £28. This being the case, it is natural to suppose that firms who had overhead wires erected before the advent of the rules feel vexed. In the case of Messrs. Crompton, an installation at Chelmsford, having thirty-nine miles of conductors, is, as the rules stand, illegal. The Brush Company, the English representatives of the Thomson-Houston system, have also overhead wires which are affected in the same way. Another rule makes the use of suspenders necessary, although it is held by contractors that they answer no useful purpose whatever.

It was finally decided by the Chamber of Commerce that further pressure should be brought to bear on the officials of the Board of Trade, and in the event of this not having effect the question will be brought forward in the House of Commons.

I gave a few particulars in my last letter about the Metropolitan Electric Supply Company culled from their annual report. At the meeting held last Friday the chairman, Sir John Pender, made some very interesting remarks. At the previous meeting held six months ago they were supplying current to 15,000 lights consumed by 58 customers. Now, they supplied 40,000 lights to 300 customers, a far larger number than was supplied by any other company in the United Kingdom. They had contracts in hand for 10,000 more and applications were made every day. The area in which this company works has on its surface the principal theatres, and everyone takes a heavy supply of current. Testimonials were read from the managers of these places and all expressed the utmost satisfaction with the light. The following table of this year shows a great increase. In March they had 16,000 lights, April, 19,000; May, 21,000; June, 22,000; July, 23,000; August, 30,000; September, 33,000; October, 36,000; November, 40,000. The detail work showed the same satisfactory state, and though the company do not declare a dividend it is said they have made £10,000 during the past six months. The doings of this company I may add are watched with great interest over here.

The annual dinner and soiree of the Institution of Electrical Engineers will be held next week. Among those expected to be present are the Postmaster-General, Attorney-General, the Presidents of the Royal Society, Chemical Society, and the Institution of Mechanical Engineers.

The French section of the telephone line and cable, which is to connect London with Paris, has been completed. It consists of two bronze wires parallel, and crossed at intervals to diminish the effects of induction. There will be direct telephone communication between London and Marseilles, and London and Rome.

The daily journals here announce that the Halifax and Bermudas Company's cable has been duly tested and a certificate granted by the government.

According to statistics there are twenty-one central electric lighting stations in Germany. The horse-power employed is 20,975.

The management of the Royal Hungarian State Railway has resolved to introduce the electric light in their trains. H. S.

LONDON, Nov. 12th, 1890.

INSPECTION INVITED OF THE NEW YORK TELEPHONE EXCHANGE.

So far from holding its patrons at a distance, the Metropolitan Telephone and Telegraph Co. invites them to learn for themselves how the work is done, so that with fuller knowledge there shall be an appreciation of the efforts made to maintain every department at the highest efficiency. Mr. David B. Parker, the general manager, has issued the following pleasant circular :

You are cordially invited to visit, at your convenience, our Exchange at 18 Cortlandt street. We think you would be interested in witnessing the practical working of the telephone system in our operating room, where the largest and most expensive switch-board ever constructed is in use, and we believe the visit would result in mutual advantage in our relations. An exchange of suggestions as to use of the telephone, between officials of the company who are devoted to the subject in hand, and subscribers who are relying upon the telephone system as an important business necessity or social convenience may contribute toward improvement in service.

CORRESPONDENCE.

CHICAGO.

The Forsyth Electric Elevated Road.—Electric Light Consolidation in Milwaukee.—The Love Electric Traction Co.

A NEW system for elevated roads to be operated by electricity has recently been devised by R. C. Forsyth and a company has been organized to build a line from East Chicago and Hammond through the Calumet district, to connect with the down-town cable lines and use this system. A working model has been completed and is to be seen in operation in one of the rooms of the Rookery. It is proposed to obviate the objectionable features of the present systems of elevated roads by doing away with the heavy upright posts and overhanging structure. At each street corner a steel tower is erected, about 45 feet high, having four spreading columns, or legs, after the manner of the Eiffel tower. The four columns spring from the corner curbs and form a double arch over the street corner. Over these towers, a three and a half inch steel wire cable extends, forming the roadway foundation. Beneath this cable and connected to it by ties are two longitudinal iron beams which are the basis of the track. The tracks are covered by common railroad rails which are 16 inches apart. The ties and struts are so arranged that the structure is rigid and the track maintained at a uniform level. The car is of the size of a regular street car, but with the wheels upon the roof instead of under the floor. The gears of the cars are two inverted trucks of four wheels each which extend above and rest on the rails, and the arrangement of the trucks is such that in the case of a broken wheel or axle the car cannot leave the track. The wire carrying the current instead of being exposed to the weather is covered and placed between and under the tracks. The trolley wheel follows this wire and the connection is free from sleet or snow in bad weather. The stations for receiving passengers will be elevated to the level of the car and it it is claimed that by the new system the advantages gained are numerous.

Since the purchase of a controlling interest in the Edison Incandescent Light and Badger Electric Light plants in Milwaukee by the Villard syndicate, an effort has been made to secure an amended franchise from the Common Council allowing the consolidation of the two companies under one management. This has been obstinately opposed by some of the aldermen on the ground of creating a monopoly. After a long fight in the Council the amended ordinance has been ordered to a third reading, the company agreeing to furnish free to the city the electric power to operate ten of the down-town bridges thereby making a saving to the city annually of $10,000.

The Love Electric Traction Company is a new concern organized with the object of changing street car lines now being run by horse or other power into an electrical underground system. The method to be employed is a new conduit of peculiar construction made without bolts or screws and so fastened together that it can be readily taken apart to get at the wires within. A slot is used in the conduit similar to that in the cable lines and the first electrical street railway conduits built. The incorporators are Judge H. N. Hibbard, J. C. Love, and A. G. Wheeler, with a capital stock of $10,000,000. It is proposed to thoroughly test the system and erect car shops in the neighborhood of Chicago, and manufacture not only their own cars, but all the other adjuncts of the system. It is expected that cars will be in operation in the early spring.

CHICAGO, Nov. 27, 1890.

PITTSBURGH.

McKeesport Electric Railway.—The Central Electric Railway, of Beaver Falls.—A New Electric Line to Homestead.—How Electricity Has Resuscitated a Horse Road.

THE McKeesport Electric Railway Company and the Baltimore and Ohio Railway Company are indulging in a little controversy just now. All the trouble has been caused by a crossing on Main street, McKeesport. The electric railway company's line, which runs along Main street, has to traverse the B. & O. tracks on this thoroughfare, and the street railway management proposes to pave the crossing with block stone, while the railroad people desire to use plank on the crossing. Until both corporations come to an agreement on this point the electric railway company will not be able to run across the B. & O. tracks. The electric railway line is otherwise nearly completed, it requiring only the putting up of the pole line to finish the construction of the line.

The Central Electric Street Railway Company, of Beaver Falls, intends to run an electric road from Rochester to Beaver and Beaver Falls, a distance of about eight miles. At West Bridgewater a branch will extend to Rochester, across the big Beaver bridge, the Rochester end of which will be raised 20 feet, thus reducing the grade into the latter place. The work of raising the

bridge will be done by the Pennsylvania Company, which contemplates changing the grade at this place. The capital stock of the company is $60,000, and the corporation is headed by the most prominent business men of Beaver Falls. Rights of way have been granted the company in nearly all the towns in the Beaver valley.

An ordinance has been granted the Duquesne Traction Company, of this city, giving that corporation the privilege of using the tracks of the Market and those of the Grant Street Electric Railway Company as well as the tracks of the Central Passenger Railway Company. These roads will form the loop in the downtown portion of the Duquesne Traction Company's system.

The Second Avenue Electric Street Railway Company commenced a few days ago to extend the tracks of its line from the Glenwood terminus in this city towards Homestead. The latter place is a suburb of Pittsburgh, about eight miles from this city. To build an electric road to that town is connected with a good deal of expenses, it requiring the erection of a bridge across the Monongahela river. This, however, is not going to deter the promoters of the new enterprise, because they feel confident that the road will be a success from the very start. The accessibility of Pittsburgh from Homestead is at present very defective, but the proposed electric street railway will form a straight line of communication from one to the other. The company intends to have new double truck cars built for the new road, and it has been decided to run the cars at a speed by which the passengers will be taken from Pittsburgh to Homestead in 45 minutes. The management of the Second Avenue Electric road promise to have the entire road in operation by next fall.

The Second Avenue Electric road has been one of the most successful street car lines in this city since it changed its motive power from horses to electricity. The road began to run the electric cars last April. Before that it was considered one of the worst street car lines in the city, in fact nobody would patronize the company's line unless compelled to. Of course the result was that the stockholders never received any dividends on their investment, which certainly prevented them from putting any more cash into it than they could help. Since the motive power has been changed, however, the property has considerably increased in value. The stock is now quoted on the local stock exchange above par, and the fact that the management has decided to incur the expense of extending the line to Homestead proves that they must have made money. This is another evidence that where a horse car road may be a failure an electric road can be a great success.

PITTSBURGH, Nov. 14, 1890.

BOSTON.

Mr. B. S. Flanders Appointed Inspector of Wires—West End Railway Work.

AT a meeting of the board of aldermen held this week, on motion of Alderman Folsom, the confirmation of the appointment of Brown S. Flanders to be an inspector of wires under the statute and ordinance recently passed, was carried unanimously.

So great has become the immediate necessity for more power for the electric system of the West End Street Railway Company that they have ordered three more McIntosh and Seymour engines and twelve 80 horse-power Thomson-Houston generators, to be installed temporarily in the permanent boiler house of the new power station on Harrison avenue. Work is now begun on the erection of the permanent boilers, but sufficient room will be left on one side of the boiler house for the temporary reception of these engines and generators. Steam will be furnished by the permanent boilers, and the new smokestack which is all but completed will be used. It is now an assured thing that Boston will have an electric elevated road, whichever actual route may be adopted, and the plans for the construction of the road are now being made. When this project actually takes shape, there will be a necessity for about 25,000 more horse-power, and the West End Company are now giving this matter their careful consideration.

BOSTON, Nov. 29, 1890.

FRANCISCO'S "MUNICIPAL LIGHTING."

The National Electric Light Association has now issued, as voted by the members at Cape May, the paper read there by Mr. M. J. Francisco, on "Municipal Lighting." As a supplement to the paper, which has attracted a large amount of attention, is printed correspondence with Prof. J. B. Barrett, of Chicago, as to the failure of the latter to take up and answer the statements of Mr. Francisco relative to Chicago city lighting, as he had promised. Prof. Barrett, on his part, complains, it appears, of bad faith on the part of the Association in letting the Francisco paper go out broadcast, before-hand, without waiting for his statement. He says he is still ready to prepare the report on Chicago work if it is wanted.

SOCIETY AND CLUB NOTES.

BALL OF THE CITIZENS' CO., BROOKLYN.

The Aid and Benefit Association of the Citizens' Electric Illuminating Co., of Brooklyn, will give its fourth annual ball, on December 5. J. Supple is president of the association; E. Reynolds, secretary; B. F. Rush, vice-president and J. R. Barefield, treasurer; E. F. Peck and L. Duncan are trustees, and J. Duncan is chairman of the executive committee. The ball committee are T. Duffy, G. Hughes and A. J. Moran.

VISIT OF THE NEW YORK ELECTRICAL SOCIETY TO AN EDISON STATION.

On Tuesday evening, November 25, the New York Electrical Society made a visit of inspection to the fine Twenty-sixth street station of the Edison Electric Illuminating Co. They mustered in good number and were received by Mr. R. R. Bowker, vice-president of the company, who made an interesting address of welcome detailing the work of the company, the scope of its service and supply, and touching upon various points of station equipment. Mr. John Van Vleck, the chief electrician of the company, with others of the staff then took the visitors in hand, and starting from the top of the building escorted them in parties through every floor, explaining all the special features of interest in each department. This occupied some time, as an opportunity of such a kind is rarely afforded. When the visitors reassembled on the dynamo floor, they were given an excellent collation, the hospitality of the company being in this respect, as otherwise, of the most cordial and profuse nature throughout the evening. Due acknowledgments were tendered to President Spencer Trask and his associates, by Prof. F. B. Crocker, Mr. C. O. Mailloux and Dr. Otto A. Moses, in the name of the society, as its officers, for the kindness and attention shown the members.

DINNER AT THE NEW YORK ELECTRIC CLUB.

A dinner will be given at The Electric Club, Thursday evening, December 4th, costing $2.00 per plate, exclusive of wines. Each member is entitled to bring one guest, and notice must positively reach the club not later than Wednesday morning, December 3d. There will be after-dinner speeches, and music, etc., provided by the committee on entertainment. It is the intention of the committee to have these social occasions alternate with the regular monthly lectures of the club, which occur every third Thursday

ELECTRICAL DEPARTMENT, BROOKLYN INSTITUTE.

On Friday, December 5th, at 8 P. M., a lecture will be delivered in the lecture room of the Y. M. C. A. building, by Mr. Ralph W. Pope, secretary of the American Institute of Electrical Engineers, on "Electrical Engineering: Its History and Possibilities." The lecture will be interesting and is likely to attract a large audience.

COLLEGE NOTES.

NOTES ON ELECTRICAL ENGINEERING DEPARTMENT AT CORNELL UNIVERSITY.

At the meeting of the Electrical Association on the 10th Nov., Instructor Saunders gave his method of determining the direction in which lines of force circulate about a wire in which a current is flowing, the basis of his method being the assigning to the line of force the quality of elasticity.

On the 17th, Mr. Lindsay, '91, described the Wenstrom dynamo, a very remarkable feature of this dynamo being the low speed of 300 to 400 revolutions at which it is run.

A new belt-testing apparatus has been added to the equipment of Sibley College through the kindness of Wm. Sellers & Co. The principal feature of this apparatus is a costly dynamometer that is peculiarly adapted to practical belt-testing, and is a most valuable acquisition for the college.

Herschel, '90, is in the employ of the Thomson-Houston Co., at Boston, as draughtsman. R. G. Thompson is making an investigation of the Thomson-Houston arc machine, similar to the one made of the Stanley dynamo by Tobey and Wallbridge last year.

NASHUA, N. H.—The first electric car ever run in this city began its trips on November 21st at the yard of the Nashua Manufacturing Company. It is a broad gauge track, used to carry the finished cloth from the cloth room to the storehouse. When the road is completed it will be about half a mile long and comprise both narrow and standard gauge tracks.

REPORTS OF COMPANIES.

FORT WAYNE ELECTRIC CO.

The treasurer of the Fort Wayne Electric Co. makes the following report to stockholders of business for the six months ending Aug. 31, 1890: Sales after deducting commissions, $867,545; net profits, $161,207; surplus March 1, $172,334; total, $333,541; dividends May 15, $90,000; present surplus, $243,541. The net profit for the past six months has been over 4 per cent. on present capital of $4,000,000. By careful estimate of the value of assets the face value has been reduced more than $300,000. The increase in the number of local companies using the Fort Wayne system during the past six months was 24, making the total number at present 128. The manufacture of dynamos and lamps will hereafter be conducted at the new factory at Fort Wayne instead of at Brooklyn, N. Y., thus effecting a large saving in cost.

AMERICAN BELL AND WESTERN UNION.

The Boston *News Bureau* says:—The attacks on Western Union and the strength of the Bell Telephone are calling attention to the relations between these two properties, and we are asked the date of the expiration of the famous telephone contract, under which the Western Union sold the Edison and all its telephone patents and claims to the Bell Telephone Co. for 20 per cent. of the Bell Co.'s telephone rentals. From this source the Western Union Telegraph Co. has now an annual net income of over $500,000. This contract was made Nov. 10, 1879, as for Nov. 1. It is for 17 years, in order to cover the lives of all the then existing patents, and will expire Nov. 1, 1896. At that date there need be no quarrel, as there will be practically no instrument rental to quarrel about. The Bell Telephone Co. will then derive its income from the Long Distance Telephone Co. and from its stocks in local telephone companies, majority control of nearly all of which it now has. The Western Union, however, is a considerable stockholder in the Metropolitan or New York Co. With the Bell Telephone Co. controlling the copper wire service of the country, telephone competition will prove more futile than have the attempts to duplicate the service of the Westean Union in the telegraph field. The Bell Telephone patent first issued expires March 7, 1893. The second Bell patent, covering the magneto field, will expire Jan. 30, 1894. The serious phase of the Western Union-Bell relations lies in the fact that the Bell Telephone Co. is building a self-supporting long-distance telephone system through the country, which will give it the most perfect telegraph system, at absolutely no additional cost for construction or maintanence, except the few dollars required for telegraph keys and sounders on the telephone desks. It has been demonstrated to the satisfaction of the Bell people that a telegraph business can be done upon the telephone lines perfectly and without any interference or disturbance of the telephone business upon the same lines at the same time. The telephone circuit, which now requires two copper wires for speech between cities, will furnish two distinct telegraph wires for four Morse operators working at the same time.

A RECONSOLIDATION OF THE RICHMOND COMPANIES.

The two passenger railways and the three electric light and power companies of Richmond, Va., have formed a consolidation under the new name of the Richmond Railway and Electric Company. The deeds of sale were recorded and a mortgage of $7,000,000 to the Atlantic Trust Company was executed. The companies going into the combination are the Union Passenger Railway Company, the City Railway Company, the Virginia Electric Light and Power Company, the Old Dominion Electric Light and Power Company, and the Richmond-Schuyler Electric Light and Power Company. The new concern holds all properties of the original companies and assumes all indebtedness. The mortgage given the Atlantic Trust Company secures 2,000 $1,000 gold bonds, running thirty years at five per cent. The money thus raised is to pay off a small indebtedness and improve the various plants and replace railway tracks and rolling stock.

STOCKS AND BONDS.

THE SPANISH-AMERICAN LIGHT AND POWER COMPANY, consolidated, of New York, has filed a certificate at Albany that its capital has been increased from $3,000,000 to $4,000,000. The record also states that the entire capital of $3,000,000 was issued in payment for property necessary for the business of the company and that the existing debts are $980,879.45.

THE BELDING MOTOR AND M'F'G CO., of Chicago, has filed a certificate of increase of capital stock from $1,000,000 to $2,000,000.

LEGAL NOTES.

THE PROPOSED MUNICIPAL PLANT FOR PEABODY, MASS.

The supreme judicial court heard evidence recently at Salem, on the petition to enjoin Peabody from spending money on an electric light plant. The questions raised were: 1. Whether a town may without special legislative authority incur a large expenditure for the erection and maintenance of an electric light plant for the purpose of lighting its streets. 2. Whether, if a town may lawfully do this, it may incur a larger expenditure than would be necessary for such purposes with a view of selling electric light for commercial purposes to the public generally. The defendant town introduced evidence tending to show that the committee did not propose to do more than to provide a plant for street lighting purposes, but as it is clear that the validity of the action of the town is to be determined by the terms of the vote and not by the subsequent action or the present intention of the committee, the petitioners propose to disregard this evidence altogether.

The public statutes do not authorize a town to maintain an electric light plant for the purpose of lighting its streets. In order for towns to establish water systems they have to get legislative permission. If a town can establish an electric light plant and manufacture electric light, it could have and can now establish a gas plant. Prior to this proposed action no town has undertaken to establish either a gas or electric plant. It is despotically taking the control of capital from its owners and transferring it to others. If they can embark in manufacturing, why not in mercantile pursuits of any and every description. In the case at bar the vote of the town plainly contemplated the erection of a plant for commercial purposes as well as for public purposes.

It is alleged that there is not any intention of using the plant for the purpose of supplying surplus lighting power to private persons, and that there is not likely to be any surplus power which can disposed of. It has already been determined that the constitution permits towns to appropriate money to establish and maintain a plant for lighting the streets by electricity. If it has such power, its means to be adopted are entirely within the power of the town to determine. The defendants contend that the town has power to light its streets by express statute provision and by usage.

SUIT AS TO USE OF THE WORDS "ELECTRICAL SUPPLY."

Recently suit was commenced in the United States Court against the Great Western Electric Supply Co., of Chicago, by the Electrical Supply Co., of the same city, the latter company wishing to establish their exclusive right to the use of all parts of their firm name. They were the first to adopt the name "Electrical Supply," but during recent years many other companies have taken practically the same name and there has resulted a confusion, which, it is claimed, is detrimental to The Electrical Supply Co. This company intend also to bring suit against other companies using the words "Electrical Supply," and hope to establish a precedent through the courts as to their titular rights.

NEW ENGLAND SHOE AND LEATHER ASSOCIATION vs. EDISON ILLUMINATING CO., OF BOSTON.—COMPULSORY SERVICE.

The State Board of Massachusetts Electric Light Commissioners has rendered a decision in the case of the New England Shoe and Leather Association and others against the Edison Illuminating Company, which is important both in itself and as a precedent. The Shoe and Leather buildings on Bedford and Kingston streets each contain steam power and an electric light plant with incandescent lamps. The petitioners desire the current from the Edison wires when the dynamos in the building are not running, and especially after six o'clock in the evening. The Edison Company objected to supplying the current, chiefly on the ground that the buildings are not furnished with Edison lamps. It put in evidence a contract dated Jan. 26, 1886, with the parent Edison Company, whereby, as it claims, it agreed not to use or supply current for any but Edison lamps.

The commission holds, however, that the provision in the United States Constitution prohibiting a State from passing any law "impairing the obligation of contracts" does not diminish the police powers of the Legislature, and, therefore, that a company chartered for the express object of selling light and electricity, and given the privilege of occupying the highways with its wires and structures, should be under obligation to furnish the same when it can conveniently be done.

AYER, MASS.—The Ayer Electric Light Co., Dr. B. H. Hartwell, president, intend taking immediate steps toward putting in a system to comprise Ayer, Shirley and Groton. The Groton Episcopal School will also be supplied.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOV. 25, 1890.

Alarms and Signals ;—

Elevator Signaling Apparatus, R. P. Garsed, 441,150. Filed May 6, 1890.

An annunciator in elevator, a series of flexible conductors from the annunciator to a fastening point in the wall of the shaft, and from thence to actuating devices upon the several floors, a supporting bracket having a flange with poles for attachment thereon, and a flared and channeled part or parts for holding the conductors in place.

Electrical Call, Lighting and Alarm System, C. A. Hale, 441,157. Filed Dec. 28, 1889.

A system of circuits, switches, annunciators and bells, especially designed for hotels, whereby the following results may be effected: A call by a guest in any room to the office; a call to any room or to all the rooms from the office; automatically sending a call to any room, or any number of rooms, at any given time; sending a call to any room or any number of rooms from the office at will and simultaneously lighting the gas or electric lights in such room or rooms; automatically calling one or more rooms and lighting the gas or electric light therein at any given time; sounding an alarm on one or more floors simultaneously and automatically turning on the light on such floors on which the alarm is sounded.

Annunciator, C. W. Holtzer, 441,304. Filed Aug. 19, 1890.

Details of construction of the frame work for supporting the magnet and armature and the drop in the proper relations to one another, and to secure certainty of operation.

Distribution :—

Device for Transforming and Controlling Electric Currents, O. A. Enholm, 441,542. Filed Feb. 20, 1890.

Obviates the excessive sparking and formation of arcs encountered in transformer systems when a pulsatory or intermittent current is employed by causing the primary circuit to be interrupted in a vacuum between solid conducting electrodes.

Dynamos and Motors :—

Armature-Body, C. A. Lieb, 441,246. Filed Sep. 18, 1890.

A series of discs of iron and insulating material, a tube through the centre of them, the ends of which are turned over or expanded against the outer discs, and stay rods longitudinally between the tube and the periphery of the disc, the ends of which are also turned over against the outer disc.

Dynamo-Brush Clamp, T. Reese, Jr., 441,256. Filed July 22, 1890.

A frame adapted to pass over and clamp the end of a brush near to the end in contact with the commutator; and particularly adapted to brushes made of several sections.

Method of Winding Dynamo-Armatures, C. E. L. Brown, 441,391. Filed Feb. 5, 1890.

Claim follows: The method of winding dynamo-armatures, consisting in winding one layer of wires upon the drum, placing a suitable continuous insulation upon said layer of wires, and then winding a second layer of wires upon the insulation, substantially as set forth.

Wire Joint for Commutators, W. E. Harrington, 441,487. Filed Aug. 28, 1890.

The commutator plate is provided with a longitudinal orifice to receive the wires which are first covered with a sleeve adapted to fit the orifice snugly; the wires are then secured in position by screws or other mechanical means. The two wires are sharply twisted upon each other after insertion into the sleeve and before insertion into the commutator.

Galvanic and Thermo Electric Batteries :—

Electric Battery Connections, H. J. Brewer, 441,130. Filed Sep. 5, 1890.

Second claim as follows: In an electric battery, the combination, with a carbon element, of a zinc connection and a metal arranged intermediate of the zinc connection and the carbon element, and of such character that it will not produce any appreciable galvanic action in connection with the carbon element, substantially as specified.

Galvanic Battery, O. A. Enholm, 441,408. Filed April 21, 1890.

A cell with an internal cup forming two compartments with a removable frame supported by the cup and insulated from it, the frame supporting both the positive and negative electrodes, one of which is insulated from the frame.

Lamps and Appurtenances :

Manufacture of Incandescent Electric Lamps, A. Bornholdt, 441,127. Filed Mar. 19, 1890.

Process of creating a vacuum with the aid of a multiple stopper—one stopper inside the other—the process consisting in first holding the vessel in inverted position allowing the auxiliary stopper to drop open, then applying the vacuum process, then reversing the vessel and causing the auxiliary stopper to close the passage and sealing the vessel.

Incandescent Electric Lamp, A. Bornholdt, 441,128. Filed Mar. 19, 1890.

Amplification of the above.

Means for Hanging Electric Lights, T. J. Lynch, 441,248. Filed Dec. 18, 1889.

An independent hook rigidly attached to the frame work of the lamp, the end of the hook being adapted to ride up over and grip the suspension cord or cable when the lamp is raised.

Arc Lamp, O. A. Enholm, 441,543. Filed Feb. 20, 1890.

Claim 1 follows: In an arc lamp, the combination of the regulator-rollers mounted on resilient supports and provided with breaking-rollers, and a carbon-holder arranged to operate in connection therewith, substantially as and for the purposes set forth.

Measurement :—

Pyrometer, W. S. Hensley and W. H. Grindley, 441,488. Filed April 28, 1889.

Claim 1 follows:

In an electric heat-measuring device, a resistance device consisting of an earthenware core upon which is wound a coil of wire and a covering of earthenware or like fire-resisting material through which the terminals or leads of the wire coil pass, in combination with a Wheatstone bridge with which the terminals of the said coil are connected, substantially as described.

Metal Working :—

Method of Electric Welding and Metal Working, M. W. Dewey, 414,401 Filed Sept. 5, 1890.

Consists in connecting the bar or blank with one terminal of an electric generator, embedding the part of the bar or blank to be worked in a yielding bed of conducting material connected with the other terminal of the electric generator, and passing a suitable heating current through the bar or blank also includes the magnetization of the bar or blank while under operation.

Miscellaneous :—

Flash-Light Photographic Apparatus, W. H. Harbeck, 441,158. Filed Apr 30, 1890.

First claim follows: In a photographic flash-light apparatus, a friction-plate, match, and match-holder, in combination with an electric circuit and magnet adapted to control such match and friction-plate, substantially as shown and described, for the purpose specified.

Rheostat, J. Doyle, 441,298. Filed Aug. 1, 1889.

Claim 1 follows: A rheostat or resistance formed of a cylinder of earthenware, having a grooved surface and resisting material in such grooves and connections for the electric conductors, substantially as specified.

Automatic Electric Gas-Lighter, L. R. S. White, 441,458. Filed May 23 1890.

For turning on and off a gas jet and when turning it on to light it.

Apparatus for and Method of Registering and Indicating the Course and Position of Marine Vessels, J. O'Neil, 441,579. Filed July 23, 1890.

Mechanical and electro-magnetic devices controlled by a revolving wheel carried upon a ship's log, whereby the position of the ship may be indicated upon a terrestrial globe on board.

Electrical Switch, G. Schultz, 441,588. Filed July 29, 1890.

A hand switch, specially applicable for use in circuits of high potential; a wide distance is provided between the contacts.

Coin-Operated Shooting Gallery, A. M. Coyle, 441,613. Filed Aug. 31, 1889.

Claim 8 follows:

The combination of the shooting device connected with its support by a universal joint, a target, an electric circuit, and a contact-maker adapted to close said circuit when the target is struck by a projectile from said shooting device, substantially as described.

Electrical Thermostat, C. H. Shaffer, 441,622. Filed May 9, 1890.

A thermostat on the open-circuit plan, held open by a link of fusible alloy; upon the melting of the link the circuit is closed.

Railways and Appliances :

Contact-Trolley for Electric Railways. N. C. Bassett, 441,122. Filed July 21, 1890.

Spring is so arranged and connected with the trolley that when the latter flies up to its highest position upon jumping the conductor it is automatically freed from the action of the spring.

Trolley for Electric Railway Cars, N. C. Bassett, 441,123. Filed July 26, 1890.

Similar to above; when the trolley jumps the wire the operating spring is automatically relieved of its tension.

Electric Street Railway System, M. Wheless, 441,210. Filed March 15, 1890.

Claim as follows:

The combination of a continuous power-line, a trolley-line composed of sections insulated from one another, a car having thereon a motor-circuit in electrical connection with the trolley-line, a local circuit, part of which containing the source of electricity is on the car, and a switch between the local and the trolley-line and power-line, whereby when the local is closed a section of the trolley-line is connected to the power-line, as set forth.

Electric Street Railway System, M. Wheless, 441,211. Filed May 3, 1890.

Amplification of the above; addition of a contact-preserver between the power-line and the trolley-line section, which maintains the contact after the local makes it and until the car leaves the section of the working conductor; also claims a continuous *insulated* power-line conductor and an uncovered working conductor in sections, insulated from one another, in combination with the other features.

Conduit for Electric Railways, M. Wheless, 441,212. Filed May 12, 1890.

Claim 4 follows:

A conduit for underground electric railway systems, consisting of brackets made with cable-standards and spaced apart, the walls of the conduit running from bracket to bracket and spaced apart at the top, cover-plates spaced apart and covering the space between the top of the conduit-walls, one of said cover-plates being permanently and the other removably secured to the brackets, as set forth.

Auxiliary Contact for Electric Railways, M. Wheless, 441,213. Filed July 14, 1890.

Claim 1 follows:

The combination of a car having insulated wheels to which circuit-wires are connected, and the line of rails with an auxiliary contact located between the wheels and the rails, as set forth.

Electric Railway Cut-Out, M. Wheless, 441,214. Filed July 21, 1890.

Electro-magnetic cut-out placed upon car for breaking a local circuit automatically when the power-line has been connected to a section of trolley line.

Insulated Brake, M. Wheless, 441,215. Filed July 21, 1890.

Claim 1 is as follows:

A railway-car brake in combination with the brake beam, the rubbing part of the brake being electrically insulated from the beam, as set forth.

Electric Railway System, M. Wheless, 441,216. Filed July 21, 1890.

Arrangement of the magneto-electric device for connecting the power-line with the working conductor sections so as to make a sufficiently wide break when the working conductor section is cut out.

Electric Railway System, M. Wheless, 441,217. Filed Aug. 27, 1890.

The claim follows:

In an electric railway system in which a local circuit operates an electro-magnetic switch in the main circuit, such local circuit having a break, in combination with a switch lever at such break, provided with a spring which normally holds the lever in the break and the rheostat in the main circuit, the lever of which crosses the switch-lever, and thereby moves the switch-lever against the spring, as set forth.

Electro-Magnetic Switch for Electric Railways, M. Wheless, 441,218. Filed Aug. 27, 1890.

Application of carbon contacts to terminals of electro-magnetic switch for connecting power-line with trolley-line sections.

Electric Railway System, M. Wheless, 441,219. Filed July 21, 1890.

Claim follows:

The combination of an insulated power-line, a bare working-conductor or motor trolley-line in insulated sections, a bare local-circuit trolley-line in insulated sections, a car provided with a motor and a battery, a trolley in electrical connection with the motor and the motor trolley-line, another trolley in electrical connection with the bat ery and the local circuit trolley-line, an electro-magnetic switch between the power-line and working-conductor, the local circuit being in electrical connection with the magnet of said switch, as set forth.

Trolley for Underground Electric Railways, S. E. Wheatley, 441,220. Filed July 21, 1890.

Trolley especially adapted to use where the working-conductor or trolley-line is in sections. Two concavo-convex brushes carried upon a yielding support and at a sufficient distance apart to insure contact with one or the other section at points of separation.

Conduit for Electric Railways, S. E. Wheatley, 441,221. Filed Aug. 28, 1890.

Claim 1 follows:

In an electric-railway system the working-conductor of which is underground, the combination of an open-slotted conduit supported upon brackets, a working-conductor in such conduit, supports for such conductor, and boxes separate and distinct from the brackets, and in which boxes the conductor-supports are secured, as set forth.

Telpherage System, J. E. Maynadier, 441,250. Filed Aug. 4, 1890.

An improvement in the system of passing the vehicle through electro-magnetic coils. The vehicle or carrier is compound, made up of a number of coils connected together by hollow couplings.

Conduit for Electric Railways, N. Seibert, 441,258. Filed March 5, 1890.

A supplemental frame hung from a railway truck and having supplemental wheels, a housing containing electric conductor, a rocking support having contacts adapted to be brought against the conductor.

Electrically-Propelled Vehicle, R. M. Hunter, 441,305. Filed Aug. 18, 1888.

Claim 1 as follows:

A car or vehicle having one or more compartments, in combination with two or more removable frames, each provided with a series of cells of battery and having two terminal contacts arranged in said compartments, hand-coupling devices movably secured within the apartments upon the car or vehicle for coupling up the terminals of the different series of cells of battery, a circuit on the car or vehicle including said battery-cells and hand-couplings, and a translating device in said circuit.

Suspending Device for Electric Wires, W. B. Marks, J. G. Lauer and R. R. Ralston, 441,312. Filed July 24, 1890.

An electrical conducting wire, a supporting wire above the conducting wire, and flexible suspenders between the posts upon which the supporting and conducting wires are sustained; the suspenders comprising an insulating portion having a transverse eye and a grooved periphery and being spaced at short intervals.

Method of Operating Electric Brakes for Electrically-Propelled Cars, W. M. Schlesinger, 441,330. Filed Jan. 28, 1888.

Consists of first cutting the car-motor out of the generator or supply current or circuit to convert said motor into a generator driven by the momentum of the car, and then successively using the armature current of the motor and the line or supply current to successively actuate said brake appliances.

Electrically-Propelled Vehicle, R. M. Hunter, 441,565. Filed Sept. 1, 1890.

Essential feature is the combination with a car and its axles of two electric motors, each of which is supported upon one side from a separate axle, the other side being supported by a yielding support connecting with a frame carried upon the axles independently of the vehicle body and arranged beneath the motors.

Electric Railway, H. W. Libbey, 441,571. Filed Sept. 23, 1889.

Claim 8 follows:

A conduit for electric railways, divided vertically into two parts, one part being slightly larger than the other and provided at its lower end with a recess forming a gutter, the two parts being each provided with a flange that are connected together by bolts, the inner surface of both sections being coated with an insulating material, in combination with two rails, one above the other, the lower rail being supported by chairs secured to the bottom of the conduit, and the upper rail by clamps that engage the upper end of the lower rail and the lower end of the upper rail, substantially as shown and described.

Electric Railway, H. W. Libbey, 441,572. Filed Oct. 9, 1889.

Consists in forming the rails hollow, covering the inner surface with insulating material, and suspending the electric conductor therein; also includes special devices for contacts between the motor and the conductor.

Secondary Batteries:—

Secondary Battery, G. E. Hatch, 441,413. Filed Feb. 13, 1890.

Object, to reduce the weight and consequent cost of lead plates as commonly employed. The invention consists in using stiff porous material, honeycombed or provided with holes, pits, grooves or depressions, both as separators and as supporters of the metal plate and in applying the active material to such porous plates instead of to the lead plates.

Telephones and Apparatus:—

Telephone, F. L. Capps, 441,396. Filed April 7, 1890.

A magneto receiver.

A permanent magnet with diaphragm mounted thereon, a vibrating armature between the poles of the magnet and connected with the diaphragm, and a stationary coil connected in the line circuit and surrounded the vibrating armature and having its axis longitudinal relatively to the armature.

FINANCIAL MARKET.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of November 29, from New York, Boston and Washington; Pittsburgh, November 28.

MR. CLARENCE E. STUMP.

There are very few people, indeed, in the electrical field in America to whom Mr. C. E. Stump is not known, and there are very few therefore who will not be interested to learn that he has become associated with the *Street Railway Journal*, of this city, and will enter upon active work as its vice-president and business manager at the beginning of 1891. That Mr. Stump should find it necessary after many years of faithful and brilliant performance of duty to quit the post he has so successfully held, must be a cause of regret and pain to his countless friends; but good work never dies, and he may rest assured that in his coming sphere of labor he will experience the reward and prosperity he has already so richly earned, though not enjoyed. Mr. Stump's selection of his new sphere is an evidence of the wisdom and judgment that, when he was free to exercise them, were the leading elements in the success of the institution he now separates himself from. The *Street Railway Journal* is a representative technical paper conducted with liberality and enterprise, and the management have the high esteem of all who know them. Among his new associates, Mr. Stump will find himself in congenial companionship, and our warmest, heartiest wishes are extended to them all.

MR. THOMAS FINNEGAN, for the last twenty years employed as doorkeeper of the operating department of the Western Union Telegraph Company in this city, died of typhoid fever last week, aged sixty-nine years. Every telegrapher in the country knew him and had a good story to tell about him. He had many eccentricities and a warm heart.

TRADE NOTES AND NOVELTIES

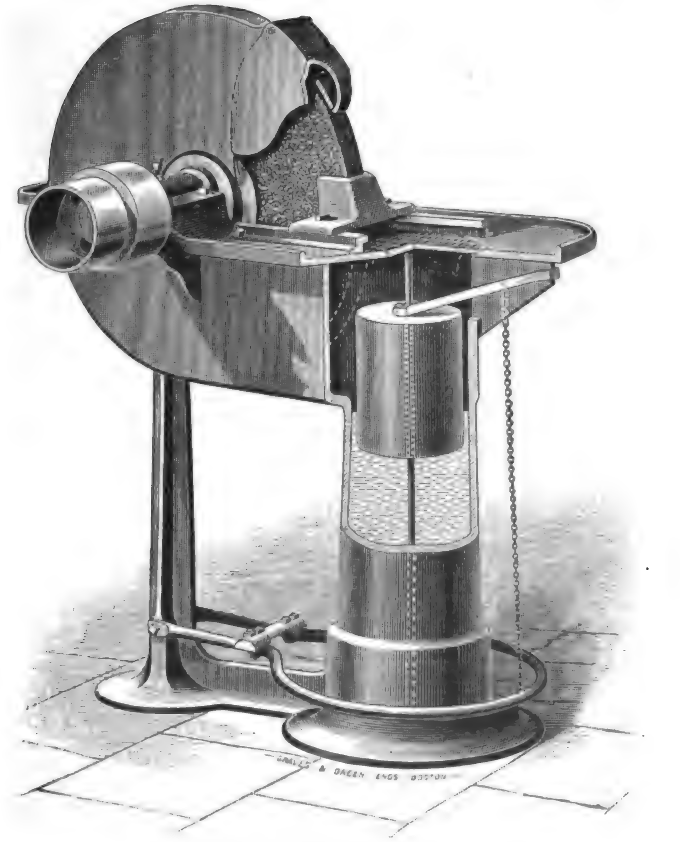
AND MECHANICAL DEPARTMENT.

THE BARNES WATER EMERY GRINDER.

The accompanying engraving represents an improved method of mounting an emery wheel, which possesses advantages which are apparent at a glance. To the front of the treadle, which is pivoted to the rear standard and bent to encircle the water column, is attached a lever, whose free end carries a float. By pressing with the foot upon the treadle, the float may be made to enter the water chamber, thereby displacing the water and forcing it to rise and supply the wheel. When the machine is not in use the float rises and the water settles back out of the way of the wheel. This arrangement does away with all pumps and valves, which are liable to get out of order, simplifies the machine, and makes it more practical under all conditions.

The chamber in which the float is suspended—resting upon the water—is divided from the chamber in which the wheel revolves by a partition, in the lower part of which is a small hole through which the water slowly enters the wheel chamber. The action of the wheel carries the water to the front upper quarter of the wheel, where it is arrested and thrown into a pocket, from whence it falls to the wheel and tool. The pocket is shown in the engraving by the outer shell broken away. Without the partition referred to, the water would be flooded into the wheel in a body or rush, which would not be desirable. The small hole being in the bottom edge of the partition, allows all the water to flow back into the reservoir when the float rises. The curved treadle can be conveniently reached, no matter what position the operator may assume when grinding.

This construction not only greatly simplifies the machine and renders it far more efficient, but it also allows it to be used in



THE BARNES WATER EMERY GRINDER.

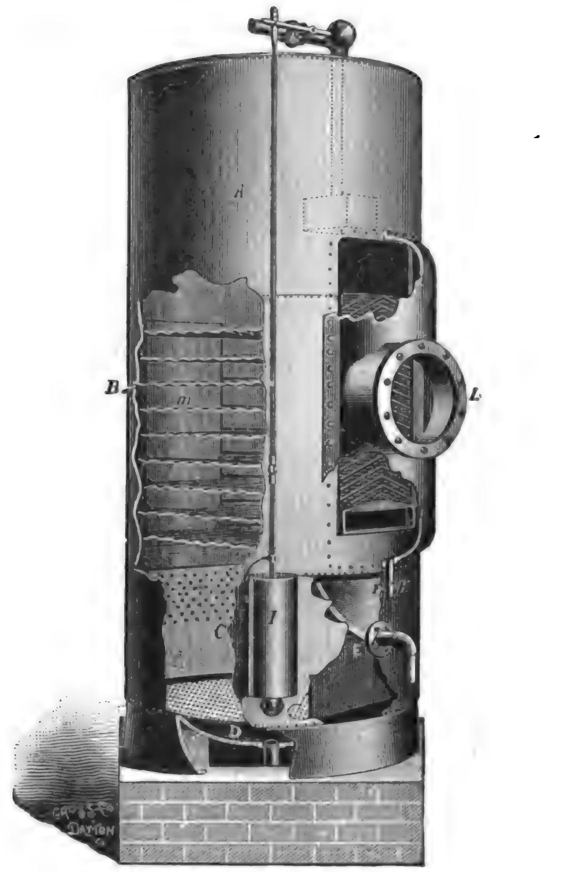
shops where there is no piping. The grinder, which is most substantially made, is built by the W. F. & John Barnes Co., of Rockford, Ill.

SCHIEREN BELTS.

Chas. A. Schieren & Co. have just furnished the Louisville Cotton Mills with 89 feet of 32-inch three-ply patent perforated belt. This is a heavy belt for one of the perforated type. The company report a growing demand for the "perforated," and have still to hear any adverse criticism from users. All who have used it speak in the highest terms of it.

STILWELL'S IMPROVED HEATER AND FILTER COMBINED.

In these days of sharp competition no steampower plant using high pressure engines can be regarded as complete from an economical point of view, unless it is provided with an efficient heater utilizing the exhaust steam for heating the feed water for



STILWELL COMBINED HEATER AND FILTER.

the boilers; and, if at the same time, the heater can be made to thoroughly purify the water so as to prevent the formation of scale in the boilers, its economical value is thereby greatly augmented.

In the Stilwell Patent Improved Heater illustrated in the accompanying engraving its manufacturers claim to offer just such a device, and they further claim to have successfully met all the objections hitherto urged against open heaters.

The characteristic features of the new heater are its very large heating and filtering capacity and also depositing surfaces for receiving the deposits of lime and other impurities. Increased facilities are also provided for quickly and thoroughly cleaning the heater and effectual devices for separating and catching the cylinder oil contained in the exhaust steam. The inflow of cold water is automatically regulated, thus insuring an even and steady feed.

A finely illustrated descriptive catalogue has been issued by the manufacturers, the Stilwell & Bierce Mfg. Co., of Dayton, O., who for more than a quarter of a century have made a specialty of machinery for heating and purifying feed water for steam boilers, a fact which entitles their claims to careful consideration.

IDE AND IDEAL ENGINES.

W. R. Fleming & Co., 174 Fulton street, New York City, agents for "Ide" and "Ideal" engines built at Harrisburg, Pa., have just closed contract for a complete steam plant for the Augusta Mining Co., of New York. The plant will consist of two "Ide" engines, boilers, etc., aggregating 100 h. p. This company are familiar with the "Ide" and "Ideal" engines, and awarded the contract without hesitation.

Other sales this week are reported as follows: One "Ideal" engine, 50 h. p., Vesuvius, Md.; one 70 h. p. steel boiler, and one 20 h. p. "Ide" engine for Chas. Avery, New York; one 20 h. p. "Ideal" for Edison Machine Works; one 30 h. p. engine for Staten Island.

A number of orders are also taken for shafting of William Sellers & Co., and belting of the Jewell Belting Co., for both of whom Fleming & Co. are selling agents.

THE GOULDS TRIPLEX ELECTRIC PUMP.

An interesting circular has just been issued on their triplex electric pumps by the Goulds M'f'g Co., of Seneca Falls, N. Y., and 60 Barclay street, this city. The pump has an extension bedplate to receive motor, and rawhide gears for the motor armature shaft and the pump countershaft. The circular says:—"In a few words the advantages and adaptability of the triplex or three cylinder pump for electric pumping (and these advantages are peculiar to our pump alone) might be best described in that *the pump offers absolutely even and unvarying resistance to motor under all conditions and consumes but minimum power in friction of parts, etc. Its efficiency challenges comparison.*

"The first effect is contributed by action of three-throw crank shaft, in whose stroke there is positively no dead centre or point of varying load productive of jerky motion and attending vibration, water hammer, etc., etc.; while the second effect is the happy result of combined ingenuity and skill in production.

"Our pump can be adapted for any make of motor, though we should be advised general dimensions of same, diameter and speed of armature shaft, and height above base."

*The horse-power is but an approximate estimate of mechanical horse-power necessary to elevate water 50 to 100 feet, running pump at 35 to 50 revolutions per minute.

THE ROCKFORD ELECTRIC MFG. CO'S. NEW FACTORY.

The Rockford Electric Manufacturing Co., of Rockford, Ill., have just got settled in their handsome large new factory on the north end corner of Fulton street and Grant avenue. The building is a commodious and handsome one, with a frontage of 50 feet and is 250 feet in depth and also has two large wings. In the front of the building are located handsomely appointed offices, fitted up with all conveniences. The factory comprises a large machine shop fitted up with all the latest and most approved machinery and labor-saving tools and devices for electrical manufacturing, and this portion is almost entirely constructed of glass, thereby ensuring the best of light. This is somewhat of a novel departure, but gives most excellent results. The testing room occupies one of the wings and is furnished with a Willans engine of 100 h. p. and a most complete outfit of testing apparatus, and so arranged that the largest and smallest machines can be tested with equal accuracy. The other wing is occupied as a wood-working and pattern shop and is equipped with all the necessary machinery for this work. A well lighted drawing office nicely fitted up is also a prominent feature. Everything in the arrangement of the whole factory has been carried out with a view to saving of labor and with signal success. The company are doing a large and rapidly increasing business and are just now placing on the market a new street railway system possessed of marked merits and worthy of careful inspection by those in need of equipments of this character.

DIRECT UNITED STATES CABLE COMPANY.

We are indebted to Mr. J. Brown, manager for this country of the Direct United States Cable Co., 40 Broadway, for a very handsome picture beautifully mounted, which can now be seen gracing our office walls. It is 24x18 in., executed in the best style of chromo lithography. In the centre is a huge terrestrial globe, across which, between the New World and the Old, Mercury and Neptune are holding a cable, their hands resting respectively on New York and London. Above this is the name of the company. The cable coils away to each side, first supporting the emblazoned arms of the United States and of England, and then forming a frame to two large sketches showing cable operators at work. Below all this, comes a list of the various offices and branches, and at the foot is a stretch of blue sea and tropical beach, all framed in the cable.

W. F. & JNO. BARNES.

W. F. and Jno. Barnes, Rockford, Ill., manufacturers of machine tools, and a house whose goods are known for their excellence all over the country, are receiving a number of remarkably strong testimonials, one of which is appended:—

ATHENS, OHIO, Nov. 4th, 1890.

DEPARTMENT OF PHYSICS AND ELECTRICAL ENGINEERING,
Ohio University, Athens, Ohio.

TO W. F. & JOHN BARNES CO.,
Rockford, Ill.

Gentlemen:—

We have at our University a steam and electrical plant and as this is extensive it necessitates many repairs. Our apparatus, too, used in chemical and physical work frequently gets out of order. Besides this we construct yearly many pieces of apparatus.

We have now in our lathe room one No. 4 lathe purchased from you some six years since and have recently added your No. 4½ lathe. I find this outfit entirely sufficient to do all the work outlined above.

Besides general work in turning, etc., I find the No. 4½ lathe about perfection for winding magnets and will use it soon for winding magnets for arc lamps. I have examined many lathes but have found none that were simpler or showed better mechanical work both in design and construction.

We use the No. 4 lathe for drilling and polishing wood and brass work. With its hand feed it is admirably adapted for working brass. Though run hard for six years it is still in excellent condition, running true and by means of the device in the head all wear has been taken up.

I regard the velocipede foot motion as the best designed for foot lathes. One can work for hours at a time without experiencing fatigue and I obtain valuable exercise and relaxation in its use.

For turning and screw cutting, the No. 4½ lathe is all that can be desired. The gears are so accurately cut that they work smoothly and with comparatively little noise. The device for reversing is not only very simple but most effective.

Very truly yours,

W. M. STINE, *Prof. Physics.*

DAVENPORT FOUNDRY & MACHINE CO.

The Davenport, Ia., Foundry & Machine Co. have just finished a 75 h. p. Meyer automatic engine for the Clarinda, Ia., Electric Light & Power Co., together with a boiler, pump and heater. They are also building a 50 h. p. Meyer automatic for the Wilton, Ia., Electric Light & Power Co., and will furnish boiler, pump and heater. They built recently a 100 h. p. Meyer engine for the Bettendorf Metal Wheel Co., of Springfield, O., to drive their machinery and several dynamos; also a 100 h. p. for the Deere & Mansur Co., Moline, Ill. They are also furnishing an electric hoist designed by Mr. H. H. Meyer for a mining company in Colorado, built on order from the Hawkeye Co., who supplied the motor.

THE CROSBY EXHIBIT AT THE INSTITUTE FAIR.

Among the electrical exhibits at the American Institute Fair, that of the Crosby Electric Co., 87 & 89 S. 5th Ave., this city, is one of the most interesting. The special feature of this exhibit is that it brings out in a most conspicuous way the multiplicity of uses to which electricity can be applied and for which this company manufactures batteries. There are the "Duplex," the "Eclipse," the "Hussey," blue stone battery and the "Crosby" dry battery, all of which are applied at this exhibit to the purposes for which they are adapted. One of the varied and many uses which this exhibit shows electricity can be applied to is a a novel cigar lighter. Two bronze figures are mounted on a pedestal. Each figure stands holding a cigarette which serves as electrode—about ⅛ inch intervening between them. A bunch of brass wire is fastened to the end of a handle and when not in use is kept in a small receptacle filled with alcohol. When it is desired to secure "a light" the torch which is saturated with alcohol is placed between the points of the cigarettes, and a current causes a spark, igniting the alcohol. The Crosby dry battery is placed in the pedestal, making it self-contained and a valuable feature not only of novelty but of permanent usefulness in any cigar store, restaurant, &c.

THE SEBASTIAN-MAY CO.

On and after Dec. 1, the well known Sebastian-May Co., of Cincinnati, O., will be installed comfortably at Sidney, O. They have issued the following notice: "It gives us pleasure to state, that owing to the rapid and continued growth of our business, we have been compelled to obtain larger manufacturing facilities (the third time within a period of seven years), and have decided upon Sidney, O., on the lines of the Dayton and Michigan and the Cleveland, Cincinnati, Chicago and St. Louis Railroads, where we have secured a large tract of land, upon which has just been completed the erection of commodious brick and stone structures, especially adapted for our business, and which we have supplied with the best and most modern machines, tools and appliances obtainable, for the rapid and economical production of our specialty lathes. This, together with the excellent shipping facilities at our command, will enable us to promptly supply any demands made upon us for our tools.

"Thanking our many customers for past favors, and trusting for a continuance of the same, we extend a cordial invitation to all to visit our new works or write us when in need of lathes or other tools."

THE WIRT LIGHTNING ARRESTER.

The Electrical Supply Co., of Chicago, have issued a neat little descriptive circular on their Wirt lightning arrester. The essential feature of the arrester is a series of plates quite insulated from each other and having a space of from $\frac{1}{1000}$ to $\frac{1}{1000}$ of an inch. The discharge is made to wear itself out in passing over all the breaks in series. The circular gives practical advice as to the right points of intercalation for the arresters in various circuits. The arresters are made in different sizes and voltages.

WESTINGHOUSE ELECTRIC RAILWAY SNOW PLOW.

A new snow plow, to be utilized upon electric street railways, is now being manufactured by the Westinghouse Electric & Mfg. Company, in connection with the Westinghouse system of electric street railway motors.

The appliance differs in a good many respects from the old-fashioned, cylindrically-shaped broom, revolving beneath the body of a truck and sweeping the snow and dirt in all directions.

The Westinghouse snow plow consists of an ordinary car truck equipped with two motors, one of which performs the propulsion of the car, while the other is used to revolve two sets of shovels. These shovels are encased in a circular box, which is so attached to the front of the truck and so designed that it glides closely over the track and the rails of the railway line. As the snow plow moves along, all the snow on the rails is picked up by the circular box. The revolving of the shovels brings the snow to the top of the case, where it is emitted through a spout. This spout can be adjusted with the opening turned towards either side of the car.

The snow plow can be operated night or day, because it is without the objectionable features of the ordinary snow sweeper, which makes a great deal of noise and interferes with the regular traffic upon the streets, as well as being an annoyance to pedestrians. It is of neat appearance and most solidly built.

ELECTRIC LIGHTING IN THE ASHLAND MINE.

The Westinghouse Electric and Manufacturing Co. has just completed the installation of an electric light plant in one of the iron mines of the Lake Superior district. The mine is called the Ashland, owned by the Ashland Iron Mining Company, of Ironwood, Mich.

There are over two thousand people occupied in the mine, which is one of the oldest and richest in the Ironwood mining district. Like most of the mines in the Lake Superior iron ore belt, the Ashland is in some portions considerably damp, and the installation of an electric lighting plant presented therefore a great many difficulties owing to the trouble of accomplishing a thorough insulation of the wires.

The Ashland is 720 feet deep and has eight levels. The descent into the mine is made by means of a number of ladders, each of them being 75 feet in length. The dampness in some parts of the mine was extraordinary, and to succeed in making the insulation perfect, the wiring had to be drawn through Simplex insulating paint, and only the best Okonite was used in the entire plant. The work could only proceed very slowly owing to these obstacles, and it took four months to finish the construction of the wiring.

The generating station of the plant is situated in the pump-house. The plant has a capacity of two 300 light Westinghouse machines. The switch-board is very artistically arranged and is made of a beaten board of white and brown birch wood.

THE MASON BATTERIES.

On Tuesday, Nov. 18, at Old Christ Church, Fifth avenue, and 35th street, N. Y., a private view of a new painting, "The New Ideal of the Christ," was afforded representatives of the press and friends of the artist. The picture was 9¼ x 12½ feet, and was lighted by a 32 c. p. incandescent light which had been chosen for its steadiness. This light was run by the well-known Mason battery, 16 of the No. 11 cells being required. These cells were placed in position on Friday, Nov. 14, and ran, without recharge, until Friday, Nov. 21, the service each day being from 10 A. M. to 10 P. M. There was also a 25 c. p. lamp placed in the dome of the church which was connected to these same batteries. It is estimated that there were about 1,000 feet of wiring in the whole.

WESTON ELECTRICAL INSTRUMENT CO.

A visit to the works of the Weston Electrical Instrument Company, Newark, N. J., found this enterprising concern full of business, and about settled in their new and handsome quarters, 114-116 William street.

The company have every facility in the way of expert help and machinery of the most improved patterns, as well as many ingenious special tools of their own design, for the perfected manufacture of their standard voltmeters and ammeters. They are at present busy perfecting some new instruments in their present line of manufacture, which are expected will shortly be put before the public.

THE EDDY MOTORS IN THE GLOBE TOBACCO FACTORY.

We give below the full text of the letter referred to last week in THE ELECTRICAL ENGINEER in the article on "Electricity in Mill Work":

DETROIT, MICH., Nov. 8, 1890.

THE EDDY ELECTRIC M'F'G. CO.,
Windsor, Conn.

Gentlemen:—We have eight of your motors now in constant use in our factory; seven of them were put in a year ago last May, when we moved into our new building, and a new one has been added to our plant recently. These motors vary from 1 to 15 h. p., and are all giving us excellent satisfaction. They are doing their work faithfully and well, and with very little expense for attention or repairs. The transmission of power by electricity has saved us about 20 h. p. over the old style of transmission by shafting and belts. In addition, we light our factory at no perceptible additional expense. We heartily commend your motors to any who are in need of a good, reliable article.

Very respectfully,
(Signed) GLOBE TOBACCO CO.

MAGNOLIA ANTI-FRICTION METAL.

Evidence showing the great merit of the Magnolia anti-friction metal, accumulates daily. Mr. C. C. Martin, chief engineer and superintendent of the Brooklyn Bridge plant, says regarding his experience with it: "We have used the Magnolia metal for about six months on the crank pin of a 450 h. p. Wright engine, and also as packing rings on the piston rod of one of our locomotives. In both cases it has given entire satisfaction, not causing us the least trouble." The Magnolia Anti-Friction Metal Co., of No. 74 Cortlandt street, N. Y., are naturally pleased at receiving this high tribute to the value of their metal.

THE EDCO STORAGE CAR IN CHICAGO.

On Saturday afternoon, November 22nd, at 2 o'clock, at the invitation of Mr. William Hood, Western manager of the Accumulator Company, of New York, a trip was taken on the Edco storage car over the North Chicago Street Railway Company's line on N. Clark street, from the car barns to Lawrence avenue, by a large party of gentlemen. The car, under the skillful manipulation of Mr. Pfatischer, operated to perfection and accomplished on the return trip the distance of 3¼ miles in 13 minutes. It is run by 88 cells of storage battery manufactured by The Accumulator Company, and two 15 h. p. motors built by the Electro Dynamic Company, of Philadelphia, who also equipped the car with its switches and other details throughout. The car is at all times under perfect control and can be run fast or slow and stopped in a remarkably short space. All expressed themselves as delighted with the operation of the car, and a very pleasant afternoon was spent.

WESTINGHOUSE LIGHTING WORK.

The Westinghouse Electric & Manufacturing Co. received during a recent week, contracts for the installation of alternating current incandescent light plants at the following places: Manchester, N. H., 1500 lights; Cohoes, N. Y., 750 lights; Amesbury, Mass., 500 lights; Aransas Pass, Tex., 750 lights; New Cumberland, W. Va., 750 lights; Rich Hill, Mo., 750 lights.

In addition to this, the alternating current central station plant at Havana, Cuba, is again compelled to increase its capacity. The Havanese intend to furnish all the suburbs of the city with electrical illumination. They purpose to extend the plant for eight miles around the city, and, to this effect, the Westinghouse Electric & Manufacturing Co. has been contracted with to furnish a 2000 volt 750 light plant.

The Westinghouse alternating current arc light system is now being introduced in Norwich, N. Y.

ELECTRIC MINING IN PENNSYLVANIA.

The Mill and Mine Electric Equipment Co., of Pittsburg, Pa., have just completed the entire equipment of another mine with electrical mining machinery, the machinery and appliances being practically the same as those put in the Monongahela Gas Co's. mines at Willock Station, Pa., and fully described and illustrated in THE ELECTRICAL ENGINEER of Sept. 17th. The mine, the equipment of which has just been completed, is the Summerhill, of Mr. Frank Armstrong, at Woodville, Pa., and the machinery is fully meeting the expectations of both the contractors and the mine owners.

A change was made in fitting up this mine in the power

plant by substituting a 9 x 10 Junior Westinghouse engine for the two 12 x 20 Carter engines the results being fully as satisfactory; the ventilating fan is run by steam instead of by electricity, as was the case in the first mine. Though the plant has been in operation but a short time the records so far show that even better results are being attained than in the first mine.

EXTENT OF THE WESTINGHOUSE INDUSTRIES.

The extent of the operations of many of our large concerns, says the Pittsburgh *Chronicle Telegraph*, is not even approximately understood. Of all of the industries in the city, none are more important than those commonly called "Westinghouse enterprises." The frequent reference to the stocks of these concerns, and the fact that they are traded in largely, have prompted an inquiry as to the extent of the present output of the different companies. It must be borne in mind that these concerns have brought new business to this community, and have added to the prosperity of all other interests.

The Westinghouse concerns, and their gross sales for the month just passed, are as follows:

	Gross sales.
Westinghouse Air Brake Co.	$ 687,000
Westinghouse Electric and Manufacturing Co	500,000
Philadelphia Company	250,000
Union Switch and Signal Co.	70,000
Westinghouse Machine Co.	50,000
Fuel Gas and Manufacturing Co.	53,000
Allegheny County Light Co.	28,000
Standard Underground Cable Co.	80,000
Total sales	$1,718,000

These figures may be studied by every Pittsburgher. They are the result of the energy and push of one man, and represent largely, if not altogether, a line of development, outside of those for which our city and section are known. Mr. Westinghouse deserves the recognition which is so seldom accorded originators and creators of industries. Commencing with his air brakes which has brought millions into this city, and his conspicuous labors in the newest fields of electricity, Mr. Westinghouse has always stood in the fore front of industrial life, and acquired a substantial and enduring fame in the annals of progress second to that of no other man. All these business interests, reaching over twenty millions of dollars per annum, have been built up without resort to sensationalism, claptrap or misdirection of any kind.

NEW ENGLAND TRADE NOTES.

THE STANDARD ELECTRIC TIME Co., of New Haven, are installing quite a number of their electric time plants (Warner system) in factories at present, which are giving eminently good service. Amongst their more recent orders is one from the Green and Daniels Manufacturing Company, of Pawtucket, R. I., to equip their factory with one regulator and 23 dial clocks.

THE CROSBY STEAM GAUGE AND VALVE Co., of Boston, have just issued a very handsome catalogue of 135 pages of their numerous specialties in gauges, etc. The book is profusely illustrated with cuts of their well known pressure gauges, safety valves, indicators, lubricators, chime whistles, revolution counters, marine clocks, test pumps, pyrometers, salinometers, thermometers, etc., and all kinds of instruments incidental to the use of steam engines and boilers. Many of the instruments are specialties, and every engineer of an electric light station ought to have one for reference.

WESTERN TRADE NOTES.

MR. G. T. HEWES, the widely known traveling representative of The Great Western Electric Supply Company, has resigned his position and will take charge of the electrical interests of the Ironwood Mining Company, at Ironwood, Mich., and Bessemer. We congratulate the company on their selection, as Mr. Hewes' ability and large knowledge of electrical matters will be of enormous benefit to them.

THE ELECTRIC MERCHANDISE Co., of 11 Adams street, have issued a very tastefully gotten up little circular calling attention to their steel wire track brooms for electric street railways, and they are receiving large orders for these brooms every day. They are made with converging holes or perforations which bring the wires in direct contact with each other, making a solid bunch or mass of wire at the point which comes in contact with the surface of the rail. Boring the holes so that every one converges to a centre makes a scraper as well as a brush.

THE EXCELSIOR ELECTRIC Co., The Rookery, Chicago, through their agent, Mr. L. W. Moyer, have recently closed the following contracts: Geo. Benedict, Munro and Clark Sts., a 7 arc-light plant; the Brevoort House, Madison St., a 7 arc-light plant; Geo. M. Clarke & Co., a 20 arc-light plant and 100 incandescents.

A NEW DEVELOPMENT in the street railway journalistic field is the *Street Railway Review*, which will be published monthly commencing January 1st, 1891, at 218 La Salle street, Chicago, and deal with the management and construction of electric, cable and horse roads and the numerous new inventions in these important industries. It will be the effort of the publishers to present a thoroughly practical, reliable and progressive journal, completely covering the field and devoted to street railway interests. Mr. H. H. Winston, Secy. of Chicago City Ry. Co., is president; Mr. T. L. Kenfield, secretary and business manager, and Mr. F. X. Cicott, formerly director U. S. Mint, San Francisco, treasurer and editor. This force will give the new journal a distinguished prestige.

THE MCGUIRE M'F'G. Co., 122–132 N. Sangamon street, Chicago, with their accustomed business enterprise and push, are just instituting a new department in their extensive works for attaching electric motors, and their necessary gears and equipment to the trucks right in their shops, thus obviating the expense and trouble of shipping the trucks first to the electrical manufacturers and then to the purchaser, and are also arranging a testing department in connection fitted up with all the latest improvements and necessary appliances. This is an important step in advance and will certainly meet with approval.

THE ELECTRIC MERCHANDISE Co., 11 E. Adams street, Chicago, the only company in the United States making an exclusive business of manufacturing electric railway supplies for all systems, are issuing a very tastefully gotten up little circular calling attention to their trolley wire insulators, curve brackets, Englund's patent centre curve insulator, overhead switches and gears and pinions, their facilities for the manufacture of which articles are unsurpassed. Their gears and pinions are all carefully tested before leaving the factory and warranted in every respect; and their rawhide pinions are well and favorably known everywhere. They also make brasses and bearings of a special quality of metal and of the best and most durable quality obtainable.

THE CENTRAL ELECTRIC Co. have obtained patents on a new form of glass insulator, especially designed for heavy railroad work. It is estimated that this insulator will increase the insulation resistance of a line at least 100 per cent. Unfortunately, the cuts describing the article could not be obtained from the artist in time for this issue, but we expect to have them in our next.

GEORGE CUTTER, so well and favorably known among the electrical fraternity all over the country, has opened an office at 333 Rookery, where he will handle electrical specialties and all kinds of electric railway, light and power supplies of merit.

COL. C. F. DUNDERDALE, 331 Rookery, so well known among electrical men in Chicago from his late connection with the Chicago office of The Westinghouse Co., is doing a general electrical contracting business, paying attention to electric street railway, electric light and power plants. He has just closed a contract with the Broad Ripple Rapid Transit Co. of Indianapolis, Ind., to build their new street railway under his supervision. The plant will cost about $85,000, and the storage battery system of the U. S. Electric Car Co. will be used. Col. Dunderdale has several other large contracts in hand which comprise electric railway plants and central stations.

THE CENTRAL ELECTRIC Co. report a continually increasing demand for improved Candee wire, and in order to meet the demand, have stocked their warerooms with a larger quantity than ever. As an instance of their unequaled facilities for doing business in a hurry, they received an order last week for 12,000 pounds of this wire to be shipped with a rush, and the wire was at the freight depot in less than one hour after the order passed through the office.

OKONITE.—The handsome little special circulars got up by the Central Electric Company exhibiting a piece of Okonite wire that has been in use for five years, and which was referred to in these columns in a late issue, has attracted much attention, and the company has received numerous applications for specimen circulars to frame and be kept as souvenirs.

FIGURES OF THOMSON-HOUSTON GROWTH.

The *American Wool Reporter* gives facts and figures obtained from General Manager Coffin, of the company, which are well worth reading: "The company is doing a current business of over $1,000,000 per month. Its expenses, including all charges of any kind and every form of outlay, are less than $750,000, which leaves a profit of over $250,000, or $3,000,000 per annum. At the end of the fiscal year, the surplus, after paying dividends, will be over $6,000,000. . . . Reckoning the net earnings of the company at $3,000,000 per annum, there would be left of this amount, after paying the dividends on the common and preferred, $1,830,000, or, in other words, the paying 7 per cent. on the preferred and 16 per cent. on the common, will use up less than half of the company's net earnings. At the beginning of last February, the company had about 100 lines of electric railways under contract, operating over 1,000 cars. It now has 175 lines, operating about 2,000 cars. In February it had 400 incandescent companies operating between 300,000 and 400,000 lights. Now it has 500 incandescent companies, operating between 500,000 and 600,000 lights. At the beginning of the year it had 68,203 arc lamps. Now it has about 85,000."

THE
Electrical Engineer.

VOL. X. DECEMBER 10, 1890. No. 136.

THE NEW ELECTRIC LIGHT STATION AT WORCESTER, MASS.

BY A. C. SHAW.

To the electrical engineer the history of the rapid growth of the electric light industry in this country is at all times interesting. The change, in a very few years, from the practice of putting plants in any cheap and inconvenient cellar, to the present idea of erecting a suitable edifice built on engineering principles for the reception of electric apparatus, is gratifying, and I am glad to present this week, as an example of modern practice, a detailed description of the new station at Worcester, Mass., which has been generally conceded to be as fine a station as there is now in the country. The Worcester Electric Light Co. have passed through all the stages of growth, from the time when they were first located in a basement on Main street, where they remained for three years, at the end of which period they were running some 250 arc lights on the Thomson-Houston system. At that time they built a new station on High street, where in four years more they increased their business to 475 arc lights and 650 incandescent. Finding themselves again cramped for room, they determined to change their location to one in the suburbs, and to build a station which would be second to none in the country, and where they would have room to follow the natural increase of their business. Accordingly they chose a site on an old mill pond, near the present factory of the Washburn & Moen Manufacturing Co., and have erected a station which can be expected to accomodate them for many years, and where they can get an inexhaustible supply of water for their condensing engines. The work on the new station was begun in July, 1889, and the station has now been in active service for about three months. From the first it was the intention to build a station on the most advanced principles, and it was decided that compound condensing engines should be used, with the very highest economy in the consumption of coal, and the station was accordingly laid out for 2,000 h. p. capacity. The general design of the building can be seen by a glance at the sectional elevation, and the plan, Figs. 1 and 2. The main building in the front is three stories high, or rather two stories and basement, and is 200 feet long by 75 feet wide. Immediately behind the main building and in the centre is the engine room, Fig. 3, a one-story building, while behind that again comes the boiler room, so arranged that there is the least possible distance between the boilers and the cylinders of the engines. The boiler house, of which we present a plan, Fig. 2, is 150 feet long by 46 feet wide, by 23 feet high, with a monitor roof 10 feet wide and 7 feet high. In this room are eight 150 h. p. boilers, built by Messrs. William Allen and Sons, of Worcester, divided into two batteries of four each. These boilers are of the horizontal tubular type with flush front with double smoke doors and double firing doors, and are specially built to run at 125 pounds working steam pressure. They are 6 feet diameter by 18 feet 3 inches long, and have each 124 best lap welded tubes, 3 inches diameter and 17 feet long. The boilers have been built of the best homogeneous steel plate, firebox quality, having a tensile strength of 60,000 pounds, with a reduction area of 55 per cent. and an elongation of 30 per cent. All the horizontal seams have butt joints, with welt inside and out, and are triple rivetted on each side of the joint. The internal size of the firebox is 72 inches long by 72 inches wide. Between the two batteries of boilers there is a special 1,200 h. p. Victor feed water heater, also built by Messrs. Allen & Sons, and heated by live steam, there being, of course, no exhaust steam, the engines being condensing. The water comes from the condenser at 100° Fah., and is raised by this heater to 250° Fah., before entering the boilers, this method of heating the feed water being found to save about 5 per cent. on coal. The smoke-stack is 140 feet high with a 72-inch flue.

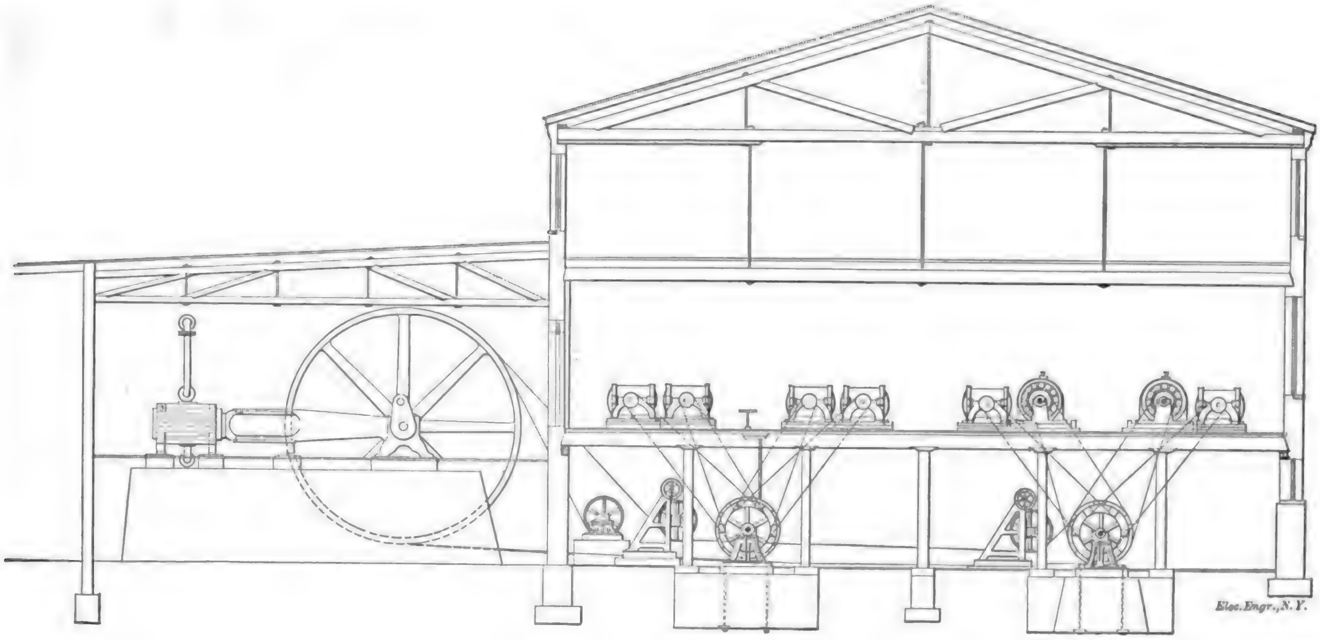

FIG 1.—ENGINE AND DYNAMO ARRANGEMENT, ELEVATION.—WORCESTER, MASS., ELECTRIC LIGHT STATION.

The motive power consists of two pairs of horizontal twin compound condensing engines, of which we present an engraving, Fig. 3, taken from a photograph of the en-

gines in the station. These engines are of the latest improved type, built by the Corliss Steam Engine Co., of Providence, R. I., and embody the latest designs and patented improvements of the late George H. Corliss, the inventor of the Corliss type of engine. The larger engine, the one nearest as shown in the cut, has a high pressure cylinder, 22 inches diameter by 48 inches stroke, and a low pressure cylinder 40 inches diameter by 48 inches stroke, connected with one another by piping and receiver. The pulley fly-wheel is 22 feet in diameter by 52 inch face weighing about 42,000 pounds, and making 70 revolutions per minute, at which speed, with 125 pounds of steam, the engine is rated at 500 h. p. The smaller engine, which is similar in design to the larger, has cylinders 18 inches by 48 inches, and 32 inches by 48 inches, with a pulley fly-wheel 20 feet in diameter by 38 inches face, weighing 35,000 pounds, and making also about 70 revolutions per minute. This engine is rated at 300 h. p. The air pump of the larger engine is 30 inches bore by 12 inches stroke, and of the smaller 26 inches bore by 12 inches stroke, each engine being furnished with a jet condenser and steam trap. These pumps are vertical with levers operated by a connecting rod, as shown in the cut, attached to the extension of the main crank pin. The cylinders are steam jacketed, neatly cased with sheet steel, and are provided with a patent safety relief attachment, for allowing the escape of entrained water. This is an important feature in the successful and safe working of these engines, and the flat spring for operating these relief valves is distinctly seen at the bottom of the nearest cylinder. Another important feature of these engines is the fly-ball governor, with which each engine is fitted, with patented improvements for obtaining more perfect regulation, and for instantly cutting off steam from the engine in case of necessity. Siebert sight feed lubricators are used throughout. The engine room is 94 feet long by 42 feet wide by 26 feet high, there being space for two more engines such as described. The gauges in the engine room were supplied by the Star Manufacturing Co., of Boston.

In the basement of the main building, which is 11 feet high, is situated the line of countershafting, Fig. 4, fitted with "Eclipse" friction clutches, the whole having been supplied by the Holyoke Machine Company, of Worcester, Mass. The foundations for the shafting are somewhat peculiar. A pit 48 inches wide and 5 feet deep, bounded by two twelve-inch brick walls, runs the whole length of the building, and is 8 feet deep under the two main bearings. Under each bearing is a 20-inch pier joining the two walls, and under the main bearings the piers are 36 inches wide. The shafting is made of steel and is 6 inches in diameter. The main pulleys run on a quill with bearings $10\frac{1}{2}$ inches in diameter, so that their weight does not rest upon the shaft, and the engines can be started up without turning the shaft. The shaft is divided into five lengths by means of four "Eclipse" friction clutches, the two for the main pulleys being 52 inches diameter, and the other two being 48 inches diameter. A belt tightener supplied by the Holyoke Machine Company is fitted to

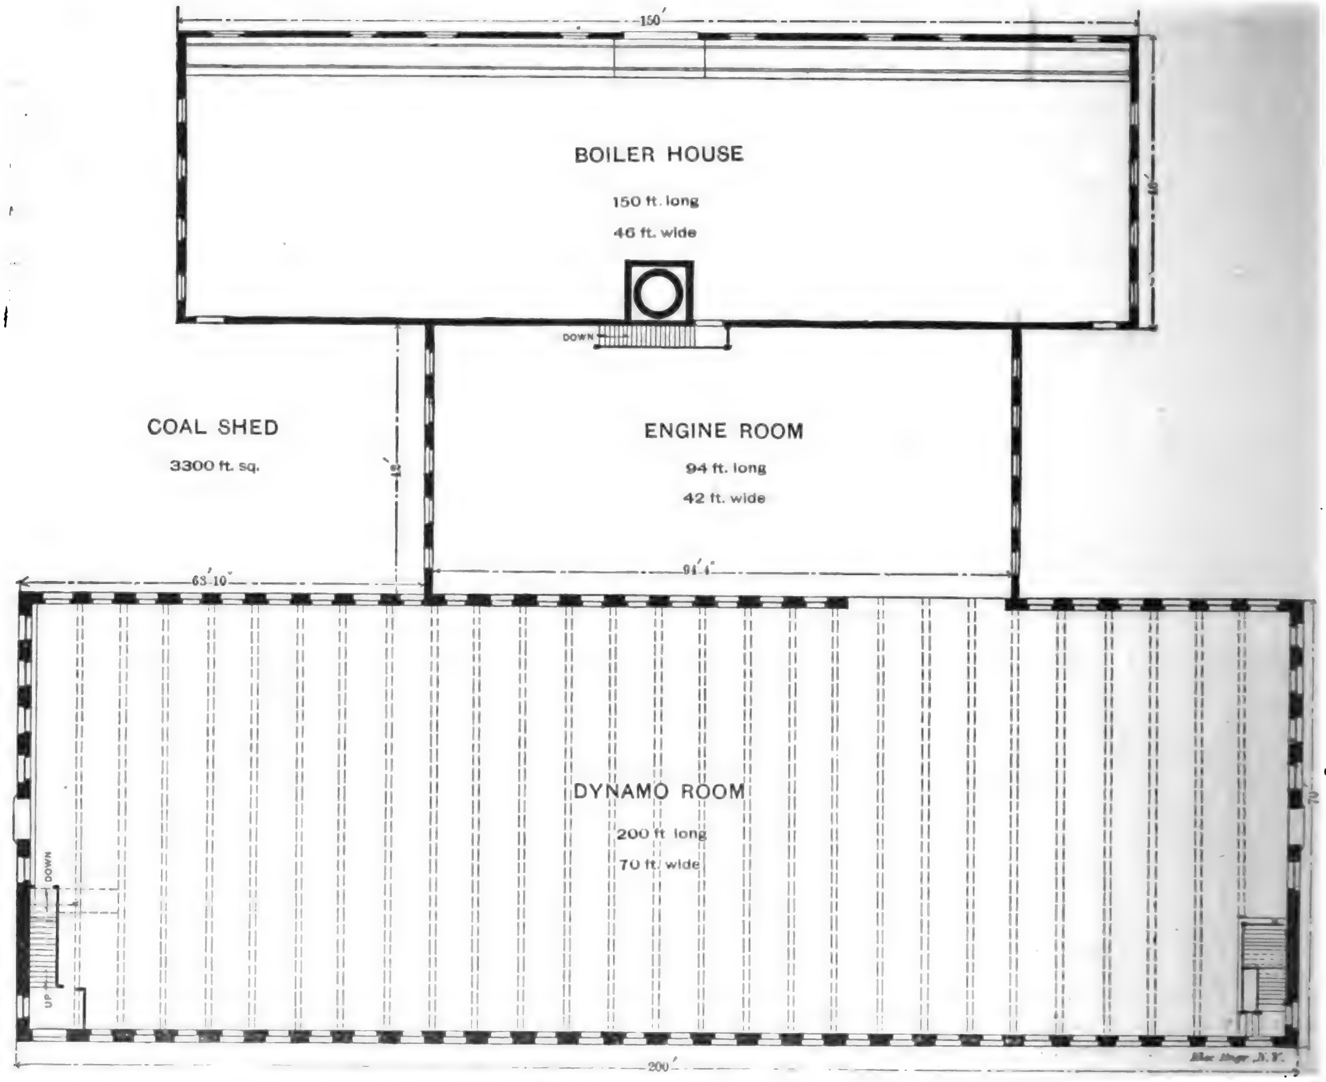

FIG. 2.—STATION OF THE WORCESTER, MASS., ELECTRIC LIGHT CO.—PLAN VIEW.

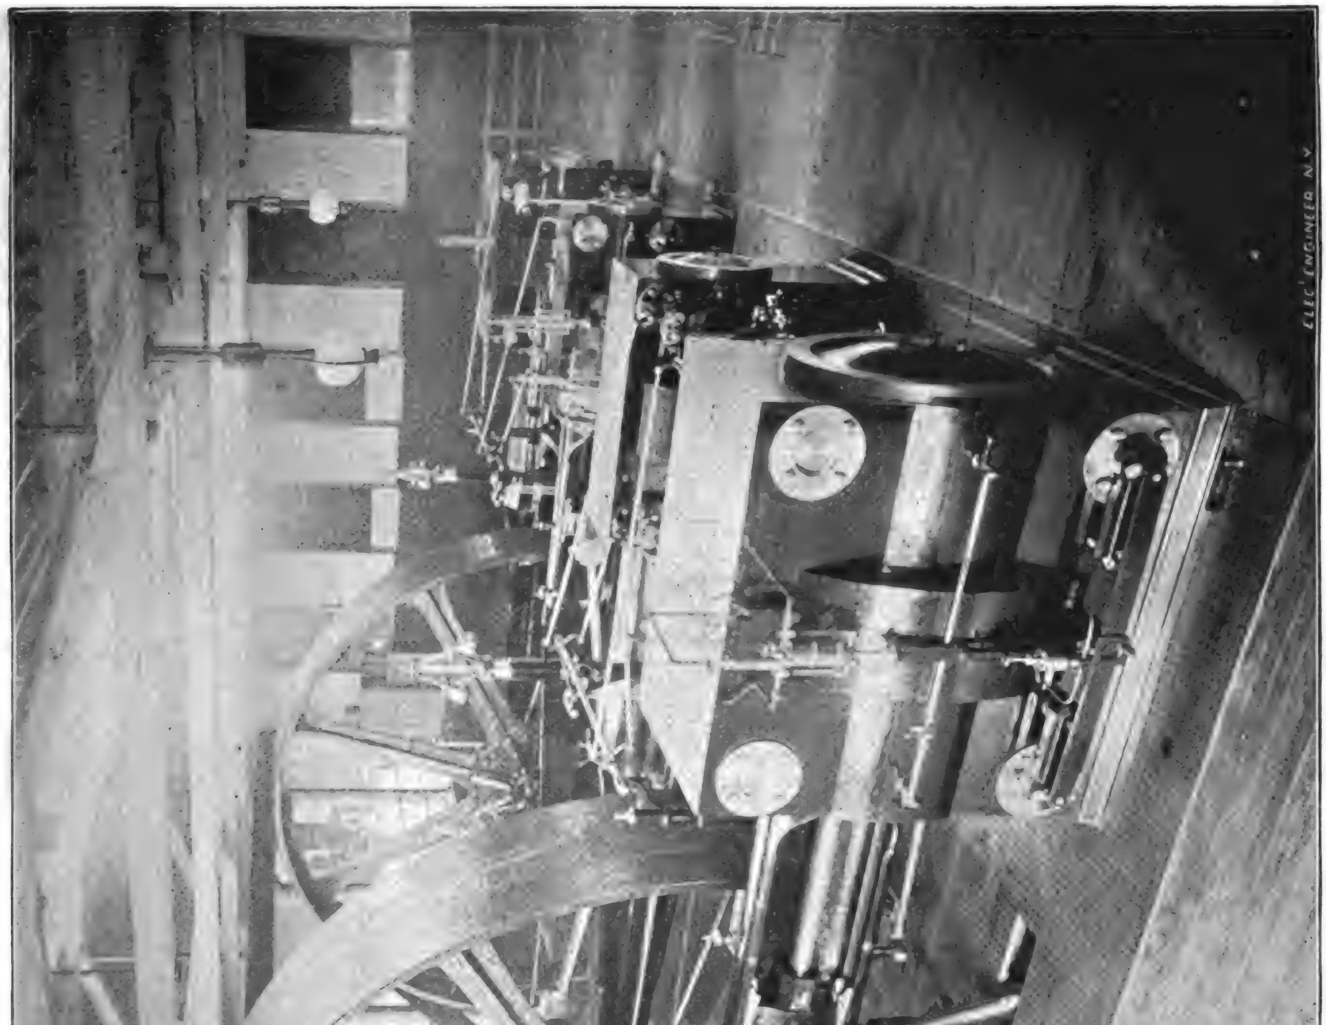

Fig. 8.– Engine Room, and Providence Corliss Engines, Worcester, Mass., Electric Light Station.

each of the two main pulleys. In the basement are 125 brick piers 16 inches square, supporting the floor of the dynamo room above. This floor consists of main timbers 12 inches by 14 inches Southern pine, 2 inch by 4 inch spruce flooring, set up edgewise, and it is finished on top by a $1\frac{1}{2}$ inch maple floor giving it a very handsome appearance. The dynamo room is 200 feet long by 70 feet wide by 14 feet high, giving a floor area of 14,000 square feet, and there is not a single post in it to mar the effect. At present there are 18 arc dynamos and two alternating incandescent dynamos installed in this room, all driven off the one line of shafting, which is capable of accommodating in all 30 dynamos. By installing another line of shafting in the basement, 30 more dynamos can be accommodated in the dynamo room, the whole capacity being for 60 machines. The switchboard is situated in the centre of the dynamo room, and embraces a 24 circuit slate switchboard of the latest type, and a skeleton switchboard for the alternating circuits. It is fitted up with all the usual instruments, voltmeter, ammeter, rheostats, ground detector, etc. The switchboard is situated directly under worthy of note that the station was started without a hitch, the engines and shafting getting down to good work at once, and the boilers being started without having a rivet sweat. My thanks are due to Messrs. Fairbanks and Coughlin for their courtesy in furnishing the above details of their work. They certainly have succeeded in providing themselves with a station which is second to none in the country, and are to be felicitated on the results.

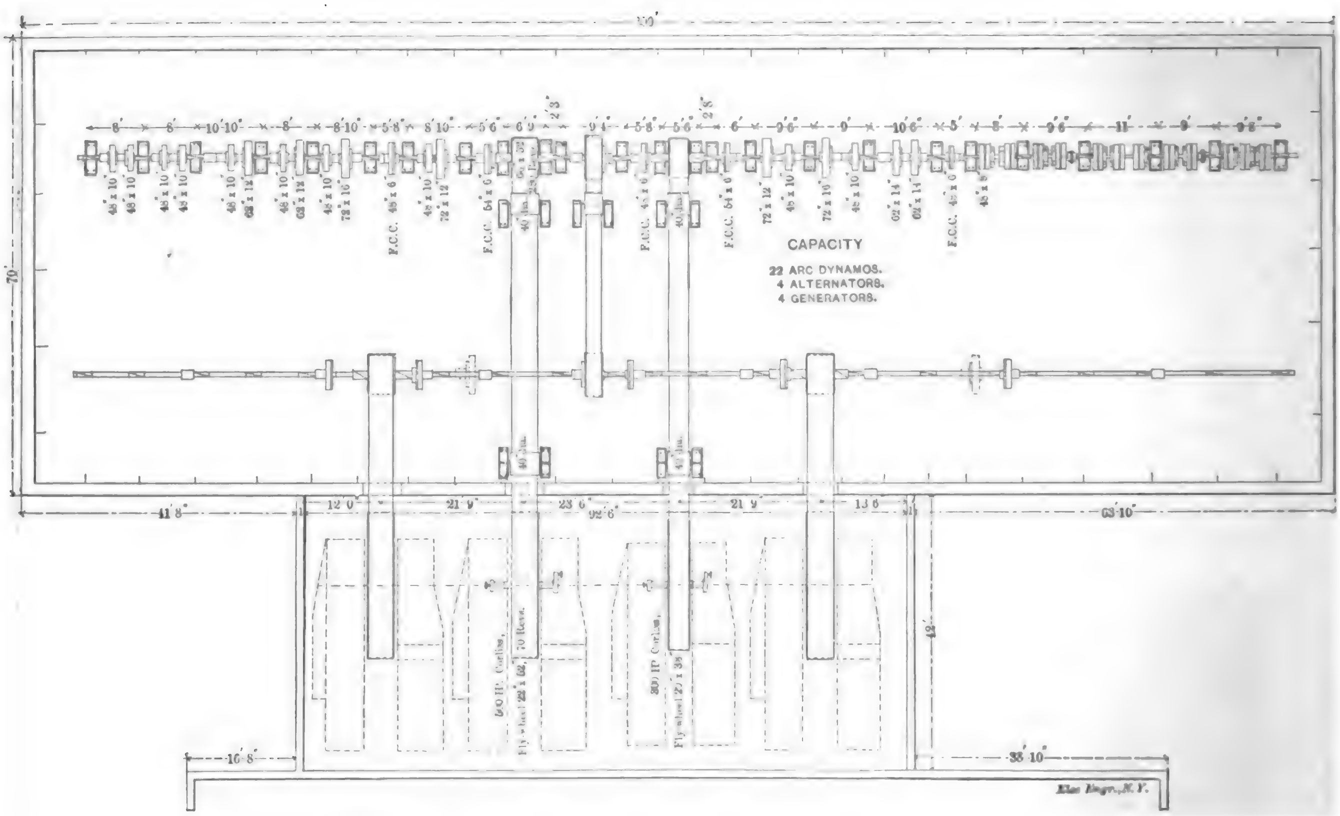

Fig. 4.—Plan of Shafting Arrangement, Worcester Electric Light Station.

the wire tower, which is 48 feet long by 14 feet wide, and which contains the lightning arresters, so that the wires run directly up and out on to the pole line, without touching the building at all.

The upper floor of the building is devoted to the offices and store rooms, of which there are ten, giving ample accommodation for all kinds of stores, which can easily be handled by means of a hydraulic elevator. A locker is also provided here for every employee.

The offices are particularly handsome, and are provided with oak furniture, and polished birch floor. The whole building is of brick, with mill finish, is well lighted throughout and presents a very attractive appearance. The general arrangement has been well designed, attention being wisely given to room for increase. At present the station is supplying current for 550 arc lights of 2,000 candle-power, and about 1,100 incandescent lamps. The whole engineering of the station has been carefully carried out, and it is worthy of note that the station was started without a hitch, the engines and shafting getting down to good work at once, and the boilers being started without having a rivet sweat.

COMPENSATING INSTRUMENTS FOR ALTERNATING CURRENTS.

Until recently there has been considerable difficulty in making alternating instruments, such as voltmeters, at moderate prices. Cheap and accurate direct-current voltmeters have been in the market for some time, but when these were tried on alternating circuits there was found an error of variable magnitude, due to the self-induction of the coils. Messrs. Goolden & Evershed have eliminated this source of inaccuracy by putting non-inductive resistance in series with the active coil, and a coil with a large time constant in shunt to it. This arrangement, which is very simply made, allows the cheap forms of electro-magnetic voltmeters to be used for alternating currents. The chief difficulty that had originally to be got over in making such instruments for direct currents was that due to hysteresis, which gives rise to errors under a decreasing pressure. This error does not come in in alternating work, so that we shall now have a still more accurate cheap alternating current voltmeter.

A CHAIR OF INDUSTRIAL ELECTRICITY.

The Minister of Commerce has just created at the Conservatoire of Arts and Sciences, a chair of industrial electricity, and the Académie des Sciences was invited to present a list of candidates for the new chair. There were three candidates for the post, MM. Marcel Deprez, Hospitalier, and Mercadier, and the President of the Republic, upon the recommendation of the Académie des Sciences, nominated M. Marcel Deprez.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—IV.

BY HERBERT LAWS WEBB.

KEYS.

THE keys in general use for cable testing are three in number; first, the *battery* key; second, the *discharge* key; and third, the *short circuit* key.

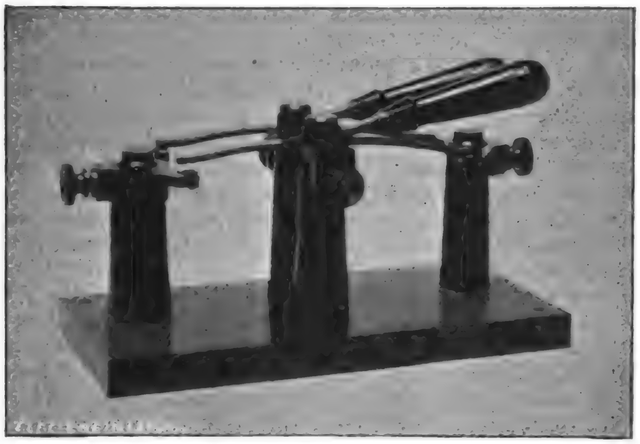

FIG. 14.—RYMER-JONES REVERSING KEY.

The form of battery key illustrated in Fig. 14 is far superior to that usually employed and shown in Fig. 15. The ordinary reversing key is both clumsy and inconvenient. If the instruments are at all crowded, the cams are difficult to get at without touching the terminals of the key, and if a powerful battery is in use this may result in the reception of a smart shock. Other objections are, that unless the workmanship is of the very best, the cams are apt to bind and work stiffly, and that the construction of the key greatly favors the accumulation of dust. As the contacts depend only upon pressure, the efficiency of the key is soon impaired by the contact points becoming dusty and dirty, while their position renders cleaning

FIG. 15.—BATTERY REVERSING KEY—OLD FORM.

a matter of considerable difficulty unless the key is taken apart.

The battery key illustrated in Fig. 14, known as the Rymer-Jones key, consists of two brass levers pivoted on hard rubber pillars and provided with hard rubber handles, by which they can be moved in one direction or the other. These levers make contact at either end with little platinum springs fixed to the ends of crescent-shaped brass plates also mounted on hard rubber pillars. To the under surface of both ends of the levers are fixed platinum contact plates. The hard rubber handle of the left hand lever is provided with a projecting lug of the same material, so that one movement suffices to throw over both the levers. The two poles of the battery are connected to the terminal screws of the crescent-shaped plates, and to the terminal screws on the pivots of the levers are connected line and earth. A simple movement of the hard rubber handles puts either pole of the battery to line, and if the handles are separated, so that the levers are free of the front plate and both in contact with the back plate, the battery is insulated and the line is put to earth through part of each lever and the rear plate.

The advantages of this key are its great simplicity—as even with the roughest treatment it would be difficult to get it out of order—and its good insulation and freedom from accumulation of dust. The contacts being made by two rubbing surfaces they are kept clean automatically by the friction from constant use. The handles are well above the terminals and contact plates, so that there is no risk of touching any of the metal parts when manipulating the key.

The *discharge key* is used, as its name implies, for discharging a condenser or cable. It has three connections,

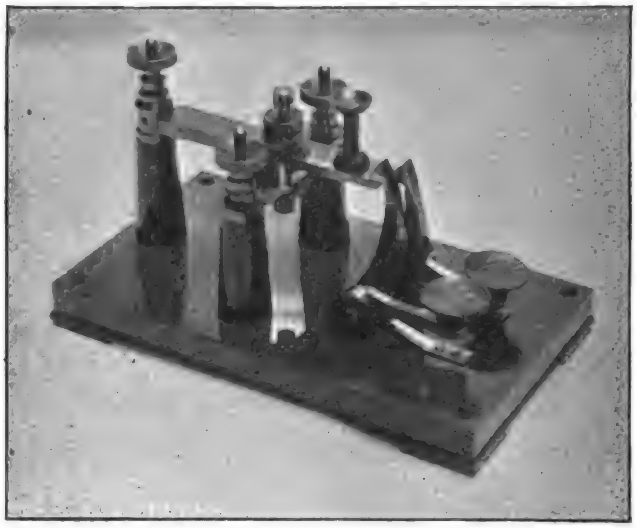

FIG. 16.—THE KEMPE DISCHARGE KEY.

one for the condenser or cable, one for the battery, and one for the galvanometer through which the discharge current is allowed to flow in order to obtain a deflection. The necessary parts of the key, therefore, are a hinged lever to which the cable or condenser is connected, a lower contact connected to the battery upon which the lever is pressed to charge, and an upper contact connected to the galvanometer, against which the lever flies when released. A trigger to engage with the end of the lever and hold it down against the lower contact for charging, or midway between the two contacts when it is desirable to insulate the charged cable or condenser, completes the key.

These necessary parts have been made up in various different patterns, among which the best and most useful are the Kempe discharge key, Fig. 16, and the Webb key, Fig. 17. In the former, a stout lever of brass, hinged at one end, plays between an upper and a lower contact; the free end of the lever, when pressed on the lower contact, is held by two triggers pivoted in front of the lever and actuated by ebonite knobs. One of these knobs is marked "Discharge" and the other "Insulate." If the knob marked "Insulate" is depressed, the lever is released from the lower contact, but is caught by one of the triggers before it reaches the upper contact; the knob marked "Discharge," when pressed, allows the lever to fly all the way up, whether it is in the insulated position or pressed

down against the lower contact. This arrangement is effected by means of an engagement between the two triggers which causes both to be withdrawn when the "Discharge" knob is pressed, while only one is withdrawn when that marked "Insulate" is pressed. The pivot of the lever and the two contact plates are mounted on hard rubber pillars.

The Webb key is of simpler construction but not quite so automatic in its movements, although the insulation is better and there is no risk of confusion, there being only one trigger. It consists of a long brass lever pivoted at one end and pressed upward against a contact by a stiff spring. Immediately in front of the free end of the lever is a hard rubber trigger, pivoted to the base of the key, carrying a projecting strip of brass, which holds the lever down when it is pressed against the lower contact. The end of the lever has a step cut in it, so that if the trigger is pulled outward slightly, the lever is released from the lower contact, but is held before reaching the upper contact by the projecting brass strip catching the step; the lever is then insulated. On pulling the trigger out a little further the lever is wholly released and brings up against the upper contact, effecting the discharge. Of course, if the trigger is pulled out sharply at first, the lever flies at

FIG. 17.—THE WEBB DISCHARGE KEY.

once from the lower contact to the upper, making the discharge instantaneously.

The reason for these attachments for insulating the lever is to enable a discharge taken after the cable has been charged, and then insulated for a certain time, to be compared with the instantaneous discharge. For instance, if a cable is charged for fifteen seconds and then discharged instantaneously, a certain deflection will be obtained; but if it be charged for fifteen seconds, then insulated for one minute, and then discharged, the deflection will be less than that obtained with the instantaneous discharge, because a slight discharge has been taking place through the dielectric to earth. In the case of a good submarine cable submerged in deep water, this difference will be very slight—about three per cent.—but in a cable having a low insulation there would be a much greater difference.

CHAIN MOTORS FOR MINES.

ONE of the latest motors designed by Mr. Albion T. Snell for coal mines obviates the disadvantages of the excessive weight of the locomotive needed to gain sufficient friction on stiff inclines, by having a continuous chain gear. The chain is fixed at each end of the gallery, and passes around the sprocket wheel of the electric motor on the locomotive, thus hauling the train of trucks along. This arrangement has been found far more practical in special cases than the simple locomotive for hauling.

PLANT EFFICIENCY WITH OPEN AND CLOSED CIRCUIT TRANSFORMERS.

BY WILLIAM STANLEY, JR.

SEVERAL contributions on the relative merits of the closed and opened circuit transformers for the distribution of electrical energy, have lately appeared in THE ELECTRICAL ENGINEER. In various letters, Mr. Swinburne has maintained that the open circuit transformer is more efficient than is its opponent of the closed magnetic circuit type, and that, consequently, American engineers were applying and advocating apparatus lacking maximum efficiency.

When, in 1885, I constructed the first closed circuit transformer, and adapted it for commercial lighting, I had in mind the very differences which are now being discussed, and at that time there seemed to me to exist certain objections to open circuit transformers which still appear to me to be of such magnitude that I believe, in America at least, the open circuit transformer is at a disadvantage. Of these objections I have seen no mention; they are briefly as follows:

In the open circuit transformer of the Ruhmkorff, the Gaulard and Gibbs, or the Hedgehog type, high efficiency is due to the fact that the fluid (or air) portion of the magnetic circuit causes the current phase to lag behind the E. M. F. more than in the closed magnetic type, and in a well constructed transformer of the open circuit type this lag is nearly 90 deg. at no load, that is, when the secondary circuit is open. Now in these transformers the value of the primary current varies comparatively little with the load derived from the secondary circuit, and when such a transformer is gradually loaded, the primary current will remain, roughly speaking, constant, while the lag of the current behind its E. M. F. will diminish; the phases of current and E. M. F. more nearly coinciding as the energy taken from the transformer is increased.

In the closed circuit type of transformer, however, the *value of the primary current in amperes* is very nearly in direct proportion to the load upon the secondary circuit. Thus, while the primary current in the open circuit type remains, roughly speaking, constant, possibly varying 10 to 20 per cent., the primary current in the closed type is proportional to the load.

Let us examine briefly the station requirements for the two contrasted types. With the open circuit type eight-tenths of the station plant, that is, eight-tenths of all the engines and dynamos, must run continually to supply the primary currents, for the ampere value of these currents is about constant; while with the closed circuit type of transformer, the engines and dynamos in service vary in proportion to the number of lamps burning. Thus, in a station having 10 dynamos and engines of equal size, in many places one dynamo and engine will easily supply all the energy necessary during twelve or fourteen hours out of the twenty-four, when the closed circuit or American type of transformer is used; while, with the open circuit type advocated by Mr. Swinburne, at least eight of such engines or dynamos would be required to do the same work. The question arises, therefore, Which system uses the least fuel, and costs the least?

For the sake of simplicity, we will allow Mr. Swinburne's transformer to have 100 per cent. efficiency. We will also allow the closed circuit transformer an efficiency of 95 per cent. which can be proven to be commercial practice in well designed transformers. Placing the engine losses at 10 per cent. and the dynamo losses at 10 per cent. and neglecting the losses in the mains, we find that with the open circuit type the loss is eight times as much as with the closed type, neglecting transformer losses; or 7.6 times, including these losses. In short, it requires about seven to seven-and-a-half times as much coal to maintain current for open circuit as for the closed circuit type, because, during the idle period of the day, approximately seven to

eight times as many dynamos and engines have to be run, and the principal losses occur in these elements instead of in the transformers. During the remainder of the day, about one-half of the time, that is, a quarter of a complete day, the efficiencies of the systems employing these two types would be equal; and during the remaining quarter of the day the efficiency of the open type would be 5 per cent. greater.

I therefore dispute Mr. Swinburne's statement that an open circuit transformer is as efficient an element of a system of distribution as its American brother. With higher frequency the open circuit transformer will make a better showing, and probably will be used, providing we can arrange means to obviate the extra losses.

By the way, why use the words converter or transformer? Would not Cyclotrope or Ergotrope, meaning that which transfers from a circuit, and that which transfers energy, be more appropriate?

AN AMPERE-FOOT TABLE FOR CALCULATING DYNAMO AND MOTOR WINDINGS.

BY LEMUEL WM. SERRELL, M. E.

About a year ago, in conversation with Mr. W. F. D. Crane, an electrical engineer well known to the readers of this journal, I was discussing different ways for quickly calculating the proper size of wire to use on dynamo electric machines. Mr. Crane suggested the use of the absolute ampere-foot, saying that he had found it very useful in his work. Since then I have worked out a complete table based upon this suggestion, and as it has proved valuable I take pleasure in giving it to the public.

The adapting of wire to various machines, to produce the desired magnetic effect, is frequently a timetaking and trying calculation. The work is comparatively small when the frame is of a standard size and the number of turns of wire of different sizes that the bobbin will hold, and the resistance of each, is known. When, however, we know that a dynamo or motor requires a certain number of ampere-feet to produce the required saturation, a table from which the size of wire to be used may be read at a glance will be a benefit to those doing this kind of work.

The accompanying is a table of absolute ampere-feet, for different sizes of wires under different voltages, and has been determined by dividing the E. M. F. by the resistance of one foot of wire, which gives the number of amperes that will flow through one foot of wire under the given pressure; or, conversely, the number of feet of wire whose resistance is such that one ampere will flow through it, under the pressure given. Thus, no matter what length of wire we use, the ampere-feet will be the same under any given pressure, and will be that given in the table. Knowing the number of ampere-feet required to produce the desired degree of saturation, we simply look in the table, in the same line that the E. M. F. to be used is given, until we find the nearest number corresponding to the required ampere-feet, and we have the size wire to be used given at the top of the column.

Let us take an example.

A 10 h. p. 220 volt C. & C. electric motor, requires 17,400 ampere-feet to produce the necessary saturation. What size wire must be used?

As the fields of this machine are in series and each requires 17,400 ampere-feet to produce the necessary saturation, the total ampere-feet on the two fields will be 34,800. We now look in the line opposite 220 volts, where we find that 34,430 ampere-feet is the nearest number to that required. Looking at the top of this column we find No. 18 wire must be used.

Table of Absolute Ampere-Feet. B. & S. Gauge.

Volts.	10,000 = $\frac{10\text{ V.}}{C}$ No. 10 wire.	7,932 = $\frac{10\text{ V.}}{C}$ No. 11 wire.	6,290 = $\frac{10\text{ V.}}{C}$ No. 12 wire.	4,988 = $\frac{10\text{ V.}}{C}$ No. 13 wire.	3,861 = $\frac{10\text{ V.}}{C}$ No. 14 wire.	3,210 = $\frac{10\text{ V.}}{C}$ No. 15 wire.	2,488 = $\frac{10\text{ V.}}{C}$ No. 16 wire.	1,973 = $\frac{10\text{ V.}}{C}$ No. 17 wire.	1,565 = $\frac{10\text{ V.}}{C}$ No. 18 wire.	1,206 = $\frac{10\text{ V.}}{C}$ No. 19 wire.	984 = $\frac{10\text{ V.}}{C}$ No. 20 wire.	780 = $\frac{10\text{ V.}}{C}$ No. 21 wire.	619 = $\frac{10\text{ V.}}{C}$ No. 22 wire.	490 = $\frac{10\text{ V.}}{C}$ No. 23 wire.	389 = $\frac{10\text{ V.}}{C}$ No. 24 wire.	309 = $\frac{10\text{ V.}}{C}$ No. 25 wire.	244 = $\frac{10\text{ V.}}{C}$ No. 26 wire.	194 = $\frac{10\text{ V.}}{C}$ No. 27 wire.

Each field magnet of this machine, in practice, is wound with 7,000 turns of No. 18 wire, and has 1,250 cir. mils per ampere of current flowing through it, which is sufficient to prevent its heating perceptibly.

Sometimes, for special windings, it is necessary to put a few more turns of wire on the armature than that calculated, in order to accommodate the wire to the size and sections of the armature. In this case, to preserve an uniform speed, it is necessary to change the field winding, and frequently the ampere-feet thus obtained will be about half way between the two nearest values found in the table. This shows that either the fields must be wound with a combination of the two wires, or a supplementary resistance must be used to produce the desired result. This is the case with the 4 h. p. 220 volt motor of the C. & C. type, the total ampere-feet of which are 15,400. By reference to the table we see that the size of

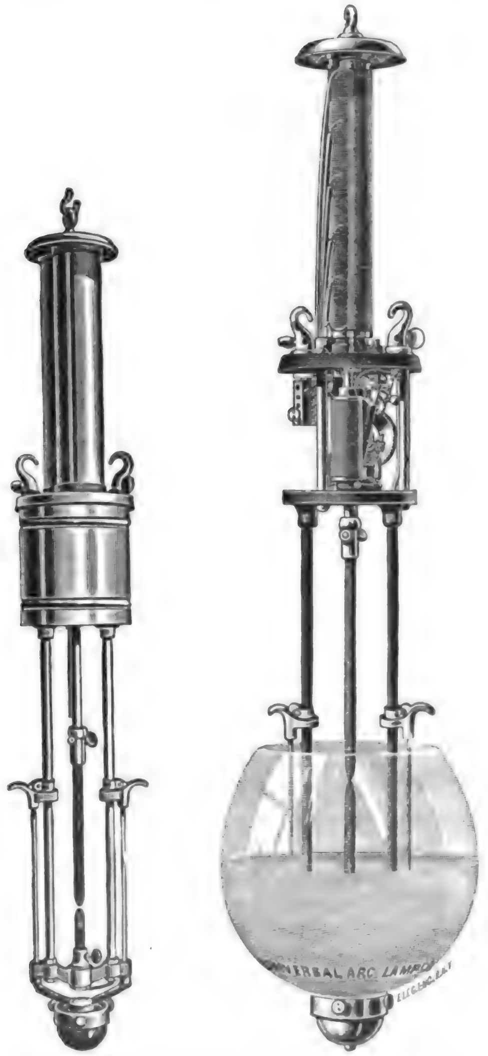
wire to be used is between No. 21 and No. 22. In actual practice the machine is wound with No. 21, and a few turns of German silver wire are wound on the outside of the field to give the required resistance.

Let us take another example. An Edison No. 6 dynamo requires 40,600 ampere-feet of wire on both fields at 125 volts. What size wire shall be used?

By reference to the table we find that a No. 15 B. & S. wire is required. In practice, No. 17 B. W. G. wire is used, the circular mils of which are 3,364 which is the nearest to a No. 15 B. & S. wire having 3,256 circular mils. The numbers given at the top of each column and designated as equal to 10 volts are multipliers by which to determine the ampere-feet for any pressure not given in the table. Thus, if we want to know the ampere-feet in a No. 14 B. & S. wire, at 136 volts pressure, we multiply 3,861 by 13.6 and obtain 52,509 as the required number.

THE "UNIVERSAL" ARC LAMP FOR INCANDESCENT CIRCUITS.

The restrictions which are being placed in some cities upon the running of overhead arc light wires, and, on the other hand, the general distribution of the incandescent current now available in nearly every city, has brought



FIGS. 1 AND 2.—THE UNIVERSAL ARC LAMP.

the arc lamp run on incandescent circuits into considerable prominence.

The nature of the incandescent circuit is such that the lamp mechanism must protect it from a dead short circuit, such as would be the case if the carbons were permitted to touch each other for any length of time. On the other hand, the lamp ought to be so constructed that it can readily be applied to circuits differing in potential within considerable limits. These qualities have been well worked out in the lamp made by the Universal Arc Lamp Co., of this city, as illustrated in the accompanying engravings.

FIG. 3.—MECHANISM OF UNIVERSAL ARC LAMP.

The lamp complete, which is shown in Fig. 1, has its mechanism enclosed within a case, the top and bottom of which are made of slate. The mechanism shown in Fig. 3, consists of a regulating magnet M wound to nearly 500 ohms resistance and allowing but .03 ampere to pass. This magnet acts upon the armature A and its strength is, of course, dependent upon the length, and hence upon the resistance of, the arc to which the magnet M is placed in shunt. As the length of the arc increases with continued burning, the armature A is attracted, until finally it trips a pawl and ratchet motion which allows the carbon to feed until it has again resumed the proper length of the arc.

The construction is such that when the carbon is completely burned the shunt magnets are automatically cut out by being released from the end of the carbon rod. Altogether there are three paths for the current from the terminal to the carbon rod so that under no conditions can sparking occur at the contacts in the mechanism. As will be seen in Figs. 2 and 3, the hood of the lamp carries within it a resistance R which is wound in sections and connected to a block of insulating material B. As before stated, provision ought to be made in lamps of this description which will permit of their being operated on circuits having different potentials. It is with the object of allowing of this that the resistances just referred to are provided. By their use the lamp can be placed on circuits varying from 95 to 125 volts. By inserting the screw S and making contact with the proper resistance terminal, the lamp can be adapted for any circuits within the range just mentioned. Thus, with the highest voltage, all the resistances would be included, while with the lowest they would all be cut out.

Another interesting feature of the lamp is the convenient means by which the globe can be removed for trimming. As will be seen in Fig. 2, the globe is supported on a circular base which is carried by two rods provided with clamps at their upper ends, which firmly grip the side rods of the lamp. By pressing the thumb upon these clamps it releases them and allows the globe to be slid down free of the carbons. Special attention has been paid to the ventilation of the hood and also of the works in the lamp. The lamps are designed to run two in series and thus to avoid the use of dead resistances and their consequent waste where only one lamp alone is used.

THE BURNET DOUBLE POLE SWITCH.

The rules of the boards of fire underwriters now generally require the employment of double-pole quick-acting switches in connection with electric lighting or power distribution within buildings, and in order to meet the re-

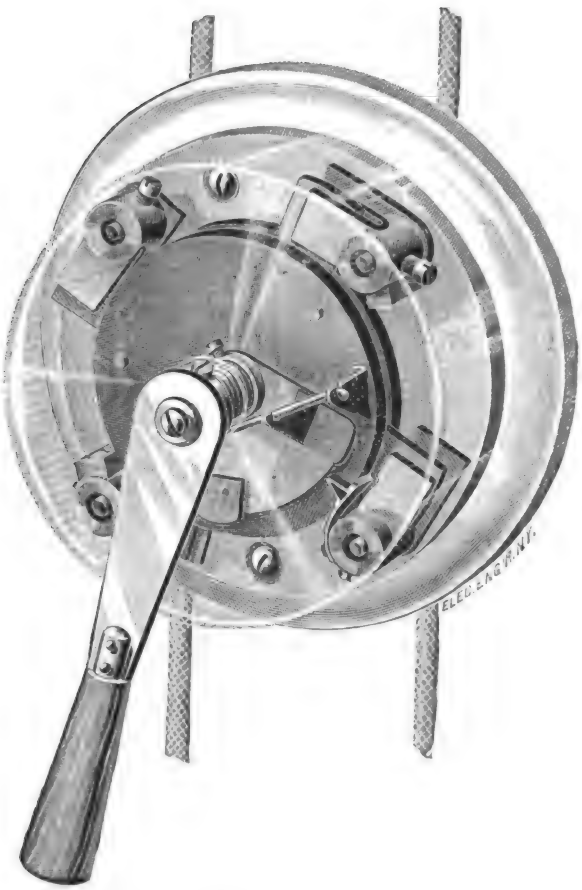


Fig. 1.—The Burnet Double-Pole Switch.

quirements in a simple manner, Mr. W. H. Burnet, of East Orange, N. J., has recently designed the apparatus illustrated in the accompanying engravings.

The switch, which is shown in Figs. 1 and 2, consists of a base upon which are mounted two discs of vulcanized fibre carrying between them the double pole contacts.

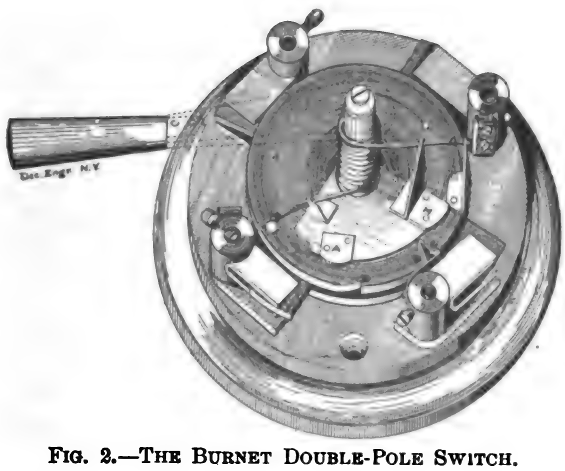

Fig. 2.—The Burnet Double-Pole Switch.

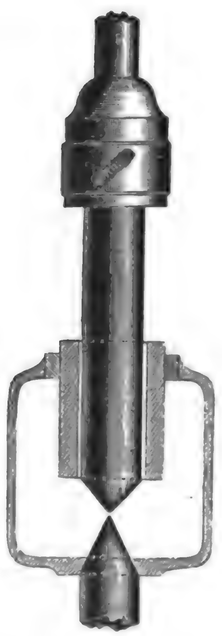
Encircling the spindle is a spiral spring, one end of which presses against the stop G and the other against the stop F. The vulcanized fibre disc is provided with notches B and C into which the latch D engages at either end of the throw of the switch. The spindle also carries a brass sector provided with cams A and E, which are arranged to pres upon the latch D.

The action of the switch will now be readily understood. In the position illustrated, the handle is turned to the left until the cam A strikes the latch D. The turning of the handle puts the spring in tension and the instant the latch is released the action of the spring throws the switch over, breaking contact at four points. When it is desired to close the switch, the handle is turned in the reverse direction until the cam E strikes the latch, when the switch is thrown back into its former position. The action of the switch gives a positive, quick break and the mechanism is of the most simple character.

THE HAZELTINE CARBON PROTECTOR.

In our issue of Nov. 12 we illustrated and described a simple device invented by Mr. C. W. Hazeltine, of the Hazeltine Electric Co., of St. Louis, for the purpose of increasing the life of the carbons in arc lamps. As then described the protector consisted of a sleeve of infusible material, which was maintained in close proximity to the tip of the upper or positive carbon, suspended from a pair of chains and maintained in its proper position by a simple pulley arrangement.

By a recent improvement the device has been consider-



The Hazeltine Carbon Protector.

ably simplified, as illustrated in the accompanying engraving. As will be seen, it now consists of the same sleeve encircling the positive carbon but supported by a ring seated directly on the negative carbon. As the latter burns away, the protector drops with it and thus constantly maintains its proper position.

Tests have shown that the life of the carbons is more than doubled by the use of the device and in its present simplified form it can be directly applied to any existing lamp.

A SIMPLE POLARITY TESTER.

Under this title we published in our issue of October 29, a note by Arthur J. Newell, describing the method of preparing paper to be used as a polarity tester, when moistened so as to conduct the current.

Referring to this, Messrs. O. Berend & Co., of London, send us a book of "Wilke's Pole Finding Paper," which is said to be in general use all over Europe and has been for the last two years. The instructions explain that when wetted the negative wire will show a red spot.

THE

ELECTRICAL ENGINEER.

[INCORPORATED.]

PUBLISHED EVERY WEDNESDAY AT

150 Broadway, New York City.

Telephone: 3860 Cortlandt. Cable Address: LENGINEER.

GEO. M. PHELPS, President. F. R. COLVIN, Treas and Business Manager.

Edited by

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. X. NEW YORK, DECEMBER 10, 1890. No. 136

Truisms which one has verified for one's self out of a personal experience are apt to have a special value to the owner.—S. P. Langley.

CENTRAL STATION EVOLUTION.

A WEEK or two ago, on the occasion of the visit of the New York Electrical Society to one of the handsome new Edison stations in this city, up town, one of the speakers took occasion to drop into interesting reminiscences of the starting up of the old Edison Pearl street station, the first of its kind in the country for the distribution of currents to incandescent lights. The difference between the two stations and equipments was so great that it was almost impossible to exaggerate or over emphasize it. That old Pearl street station in its day was thought to be monstrous fine, but its design, its equipment and its practice have been so vastly improved upon by the rapid evolution of the art, that the old station and the new ones hardly seem to belong to the same decade. A century might well have intervened between them. And the curious thing is that, admirable as are these new stations, they, in turn, are to be thrown into a second place by others the erection of which will not now be much delayed.

Arc stations, too, have seen an evolution, simple as their requirements are. One of the first and largest arc stations in this city occupied a building that had been used as a soap factory. Of course it went up in smoke and fire at last, and the only wonder is it lasted so long. Not a few stations started in damp cellars or ramshackle barns, and even those which were put into decent brick buildings were generally poor in style and of ludicrously small proportions. What has been seen in at least a hundred cities is excellently described in our columns this week by Mr. A. C. Shaw, in his illustrated article on the new station at Worcester, Mass. There we find a plant that, having started in a basement, has already been twice removed and enlarged since that time, and only to-day finds itself in quarters and under conditions of capacity commensurate with the demand for electric light, power and heat.

As far as we are aware, the conduct of the business at Worcester has been excellent from the beginning. Its rapid growth alone would vindicate this, and it is not to be supposed that in Worcester any more than anywhere else would there be an appreciation of the full possibilities of the field. Yet it would be a fair matter for inquiry, as was lately suggested by Mr. Sunny, whether, had the stations at Worcester, Baltimore, Providence, New York, and elsewhere been constructed on their present lines the return on the investment would not have been larger and steadier than it has been with this frequent and costly pulling down of the old barns in order to build new.

The station at Worcester, moreover, is an interesting one in the fact that it supplies a variety of services and that in spite of its composite nature the motive power is furnished by large engines. It begins to look as though the old, and hot, discussion among electric light men, as to large and small engine units was going in favor of the big engines, not merely for arc stations or composite stations, but for those supplying simply incandescent lights. The question is still an interesting one, however, and by and by may take another turn, or may show a struggle for supremacy, on economical grounds among the various distinct types of large engines themselves.

THE ETHICS OF TRANSLATION.

WE are heartily glad to note the action of the House of Representatives during the past week in the adoption of the principles of copyright. There is now hope that the country will soon have a decent copyright law under which the foreign author may derive some benefit from the republication of his work in this country. The technical author, *i. e.*, one writing upon technical topics, is perhaps the man who will benefit most by this, for while there is not often the temptation to reprint a technical book, because of the comparative smallness of the demand, yet when the rare occasion does arise, its returns and profits are snatched away from him, the very infrequency of the opportunities making them the more eagerly watched for by those who under existing conditions have not felt called upon to pay the author so long as the law did not enforce his claim.

The American technical author, too, may be benefited by the change. A case of "piracy" that has just come under our notice causes us to hope that American work of the brain will enjoy more protection abroad than now falls to its lot. Two writers in this country spent several months upon a work on electric motors. They made next to nothing out of it, but it has gone through several editions now and has circulated widely in Europe. A German doctor seeing its merit determined to put it into German, and accordingly is bringing out the work in serial form, with the same title, the same cuts, and apparently little other matter, utterly without acknowledgment of any kind. We are informed that in getting the translation

made, he took the American book, cut off the heads of the pages, and then gave them to another German doctor, better acquainted than himself with English but not sufficiently familiar with electricity to detect the origin of the text. The translation was made in due course, but the translator, finding that *his* humble work was not acknowledged, complained to the editor of a German electrical paper of shabby treatment, and thus the little job came out. We have, thanks to our German colleague, some of the parts of the serial in our possession and have been actually able to identify page after page, though often misplaced or rearranged, with the text exactly as it stands in the American book.

Now, possibly, even copyright in an approved form may not be able to touch such cases as this, but there should not be discouragement, for the public feeling and state of mind or conscience that calls for a just copyright law will visit such acts with condemnation which while it lacks directness in immediate punitive result will be not the less severe and salutary in the long run. The man whom people know to be a thief, in any wise, but who avoids the designation only because he is for a time able to keep his indignant victims at bay and in suspense by means of the law's inadequacy or delays, gains nothing after all but an accumulated retribution.

OPEN AND CLOSED CIRCUIT TRANSFORMERS.

It is not very long ago that discussions, and in some instances acrimonious controversies, were carried on between the adherents of the continuous and alternating current systems of distribution before the electrical societies and in the electrical journals; but we hear little of this nowadays, and hence it may be taken for granted that, though later in its arrival upon the scene of practical work, the alternating current is now accepted and firmly established as a practical commercial means of distribution. With this point determined, there have, however, recently arisen other discussions relating to the methods of distributing the alternating current itself. The design and character of the transformer itself have recently given rise to an interesting controversy carried on through our columns, by Mr. Swinburne as the advocate of the open magnetic circuit type as against the closed circuit type, of which Mr. Tesla has thus far been the able advocate. Taking up the same discussion in this issue, Mr. Wm. Stanley, Jr., the pioneer in transformer work in this country, brings an additional and weighty argument in support of the superiority of the closed over the open circuit transformer. Accepting the conditions of supply as we find them in practice, that is, with large fluctuations of load, according to the time of day, Mr. Stanley points out, that while the efficiency of conversion, pure and simple, of the open circuit type may, under certain conditions and with maximum load, exceed that of the closed circuit, the nature of the former is such that the primary current varies but very little throughout the entire range of the load; whereas in the closed circuit type, the primary current is practically in direct proportion to the energy developed in the secondary circuit. Based on this fact, Mr. Stanley's argument shows that the conditions obtaining in this country, at least, are against the introduction of the open circuit type on account of the high day engine-load which would be required at the station, and for which there would be no offsetting revenue.

We do not recall having seen a full record of tests of an open circuit transformer throughout its entire load, and we think Mr. Swinburne could throw much light on the subject thus brought forward by Mr. Stanley by submitting such a record.

An Ampere-Foot Table.

There is hardly a piece of electrical apparatus which does not embody the construction of an electro-magnet, and whereas heretofore the proportions of the magnet were to a large extent a matter of guesswork, the recent advances in the study of magnetism now make it possible to determine beforehand the properties of a magnet with considerable accuracy. While in the past the calculations, especially of dynamo electric machinery, have for the most part been made and expressed in ampere turns, it is evident that when practically applied, the ampere turns have to be reduced to a given length of wire capable of carrying a given amount of current. To simplify this calculation, therefore, and in fact to make it practically unnecessary will be recognized at once as a valuable addition to the methods of the constructing electrical engineer. The table which we give in another column, calculated by Mr. L. W. Serrell, will for this reason be welcome to many of our readers.

Electric Railway Tracks.

While it might appear, upon the surface, that electric railroading differed from horse traction merely in the nature of the propelling force, experience in the new work demonstrated from the very start that certain ulterior considerations had to be fulfilled in order to insure success. Among these there is none of greater importance to the proper operation of an electric railroad than the track itself. Electric cars must of necessity be heavier than the old type hauled by horses, and when to this we add the fact that the wheels of the electric car frequently grip and grind or plane the track in addition to the old rolling motion, it is evident that heavier tracks must be provided to withstand the added strain. This has now become generally recognized with the result that the installation of an electric railroad is generally accompanied by a new and heavier rail. But there are still some points in connection with this subject which deserve careful attention and are well brought out in the article by Mr. T. H. Gibbon, appearing on another page. The present method of track construction is certainly not one embodying the greatest economy when renewal and repairs are taken into consideration, and a method in which these items are reduced to a minimum, such as that bearing Mr. Gibbon's name, must sooner or later command the attention it deserves. Again the question of ground return wires and rail-joints is one that has by no means been finally solved. The present method of construction by reenforcement with bare copper conductors, has in many instances been found to lack permanence, on account of the corrosion of the conductors by electrolysis. A rail construction which will obviate this difficulty has thus an important additional claim to recognition and it will no doubt receive the careful consideration of electric railway operators.

THE BARRIETT ELECTRIC FAN OUTFIT.

The small space occupied by the fan driven by the electric motor has made such outfits a familiar sight, and now, to bring the machine down to its most simple and effective form, Mr. S. L. Barriett, electrician of the Barriett Electric Co., of this city, has designed the type illustrated in the accompanying engraving. The little motor, which is of $\frac{1}{16}$ h. p., embodies neat electrical and mechanical designs, which constitute important advantages in practical operation.

Thus, the field magnet is laminated with the softest charcoal annealed iron, having no joints in the magnetic circuit in the direction in which the lines of force pass. By the use of a toothed armature, the teeth of which are cut spirally, all noise is prevented and the resistance of the air gap is reduced to a minimum, enabling the use of an armature of extremely low electrical resistance. The energy wasted in heat in an armature is proportional to its resistance, and is not only important as affecting the efficiency, but also in its effect upon the cool running of the

THE BARRIETT ELECTRIC FAN OUTFIT.

motor. Besides, a low resistance armature gives better regulation, and this can only be secured by using a powerful field which can be obtained when such a field is used with an expenditure of very few watts.

The electrical design has been carefully worked out. The armature and field magnets are connected in series and for the 110 volt circuits the windings are as follows: Armature, 5 ohms; field magnets, 105. The counter E. M. F. generated is equal to 55 volts, so that the machine in operation takes only $\frac{1}{2}$ ampere.

It will be noted that on account of the high resistance of the field in series with the armature the motor can be thrown into circuit without any external resistance and runs cool without the permanent interposition of such a resistance.

When running at its normal speed of 2,500 revolutions per minute, it is capable of exhausting 156 cubic feet of air per minute.

By merely adding to the number of the plates in the field and increasing the length of the armature, the $\frac{1}{16}$ h. p. motor is converted into one of a $\frac{1}{8}$ h. p. The former has a fan 8 in. in diameter, and the latter, running at 2,100 revolutions per minute, 12 inches. Mr. Barriett is now working out designs of motors of larger powers.

THE ELECTRICAL EXECUTION DELAYED.

It appears that the last proceedings in the case of the murderer Wood cause a practical stay. Hence the date of execution is again uncertain, and the apparatus will once more have to be tested in advance on some innocent animal.

A NOVEL FORM OF MEASURING INSTRUMENT.

In a recent issue of *La Lumière Electrique*, M. F. Leconte gives a brief account of some experiments carried out by him at the Liège University with a view of testing a curious form of electrical measuring instrument. M. Leconte's idea is to make a pile of circular iron discs, interposing some springy substance between each disc, and to place this pile inside a solenoid. When the solenoid is traversed by a current, the pile of discs tends to contract owing to the formation of unlike magnetic poles at the opposing surface of the discs. This contraction is resisted by the springs, and by means of a suitable magnifying device the movement of a pointer along a suitably graduated scale enables one to read off the volts or the amperes. M. Leconte employed discs ranging in number from 18 to 60, in diameter (1mm. = 40 mils) from 20mm. to 65mm., and in thickness from .2mm. to 8mm. Amongst the substances employed as springs were watch-spring steel, blotting paper, packing paper, ordinary paper, flannel and black india rubber. The tendency of the discs to move sidewise was checked by punching holes through them and slipping them over vertical glass rods. The sensitiveness of such an apparatus can be increased either by adding to the number of the discs, augmenting their surface, or by providing the solenoid with a core of iron wire. M. Leconte gives curves of the scale readings obtained with a voltmeter arranged with 18 cast-iron discs, 8mm. thick, and 65mm. in diameter, and provided first with india rubber springs and then with steel springs. The curve in the first case was fairly regular between 27 and 53 volts; with steel springs the curve was very irregular; with india rubber springs the deviation of the scale index was only 18mm. for 57 volts, and the actual contraction of the column of discs was only 2mm.; with steel springs the index deviation was only 8mm. for 50 volts.

THE NEW SOUTH AMERICAN CABLE.

The cable steamer *Silvertown* arrived at Valparaiso on Dec. 1 from London, having on board the submarine cable to be laid between Callao, Peru, and Valparaiso, Chili, for the Central and South American Telegraph Company, of New York. Soundings will be taken on the northward trip, and when completed the cable will be laid from Callao to Iquique, thence to Valparaiso. Its opening about January 1 will be followed by a reduction in commercial and press rates to all places in Chili and Argentina. Many of the restrictions, such as double charge for code messages and a fee for registration imposed by the English companies, will not be enforced by the American company.

SECRETARY TRACY ON THE ELECTRICAL CORPS.

Last week we alluded to the reference in the report of the Secretary of the Navy to the electrical corps, proposed by Lieut. B. A. Fiske. The passage, in full, is as follows:

"In connection with the subject of a naval militia, I would call attention to the advantage of providing a place in its ranks for persons of special acquirements demanded by the naval service, but of a character somewhat outside of the ordinary scope of professional training. The extensive employment of electricity in its applications on shipboard makes it necessary for naval officers to acquire a certain amount of electrical knowledge, but it is impossible for all, or even for any great number of them, to become expert electricians, nor is it desirable that they should do so at the expense of other branches of their profession of more pressing importance. To meet this want, it is suggested that a corps of naval electricians be established in the different States that have created a naval militia, to be attached to this militia and to receive the naval training which it is the great object of the militia to give.

"By this means a corps of electrical specialists would be organized, familiar with the needs and usages of the naval service, and the extended applications of electricity to naval vessels would be rapidly developed in time of peace as well as in war. In the latter contingency the corps would be especially valuable in fitting out new vessels with electrical apparatus and in taking charge of the electrical plant on board ships in commission. The number of officers available in an emergency would thus be increased, as those now detailed to electrical work could be assigned to other duties and their work could be carried on by the experts of the naval militia."

THE JEFFREY ELECTRIC COAL MINING APPARATUS.

THOUGH but a comparatively short time has elapsed since the benefits accruing to mine operators by the employment of electricity have been shown, enough has been accomplished to demonstrate not only the thorough practicability of the various types of electric apparatus, but their economy also. This refers as well to the lighting of mines as to the transportation of the product mined by electric motor cars, and its bringing down by electric drills.

Among those who have devoted considerable attention to the application of electricity to mining purposes, and especially coal mining, are the Jeffrey Manufacturing Co., of Columbus, O., who have utilized their long experience in coal mining machinery to good advantage in the new class of work. As a result, they have produced and already installed in a number of places the coal mining machine illustrated in the accompanying engraving, Fig. 2, page 650.

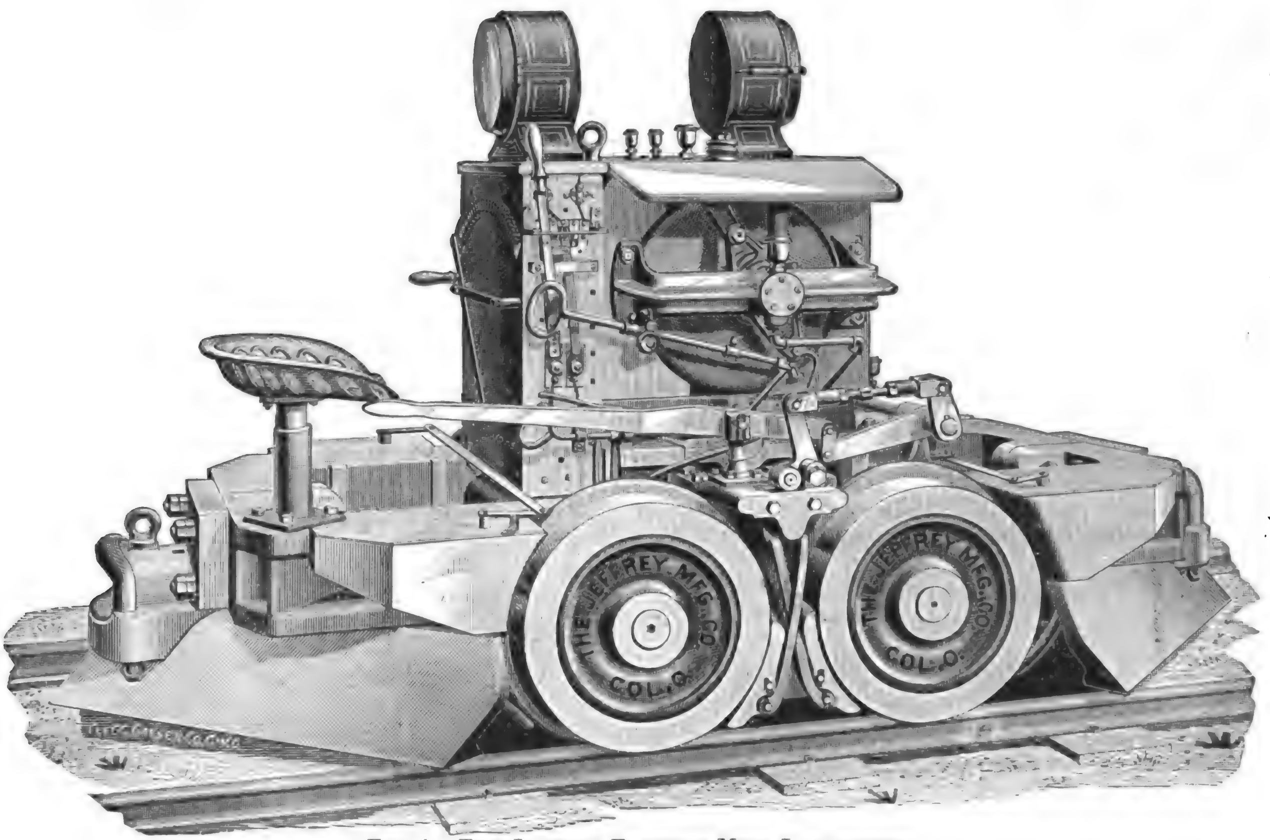

FIG. 1.—THE JEFFREY ELECTRIC MINE LOCOMOTIVE.

The machine consists of a bed frame occupying a space two feet wide, by seven feet six inches long, composed of two steel channel bars firmly braced, the top plates on each forming racks with their teeth downward, into which the feed wheels of the sliding frame engage. Mounted upon, and engaging with, this bed frame is a sliding frame, similarly braced, consisting mainly of two steel bars, upon which are mounted at the rear ends, an electric motor, from which power is transmitted through straight gear and worm wheel to the rack, by means of which the sliding frame is fed forward. Upon the front end of this sliding frame is mounted the cutter-bar, held firmly by two solid steel shoes, with brass boxes. The cutter-bar contains bits, made of tool steel, held in place by set screws. When the cutter-bar is revolved, these cutters or bits cover its entire face. The cutter-bar is revolved by an endless curved link steel chain from the driving shaft, and as it is revolved, is advanced by the mechanism into the coal or other material, to be under-cut to the desired depth.

The motor occupies a space of about 20 inches square, is built in the most substantial manner, and has an efficiency of 90 per cent. The current required is from 30 to 50 amperes at a pressure of 220 volts; each motor is wound to develop fully 15 h. p., though frequently in some veins of coal the machine only uses 30 amperes or 8½ h. p. in making cuts. The machine is started by means of a switch located on a resistance box, on the rear end of the motor.

The armature of the motor is calculated to run at a speed of 1,000 revolutions per minute, from which the speed is reduced, so as to run the cutter-bar 200 revolutions per minute. The momentum of the armature is such, that ordinary obstructions met by the cutter-bar in the coal are not perceptible, causing the machine to run steadily and comparatively quiet.

The machines are operated by two men, one man in charge and the other as helper. Trucks are furnished with the machines, which enable them to be handled with ease. The machine is taken into the mine upon this truck and run into the room to be under-cut. It is then placed on two boards in front of the coal at one side of the room, and is fastened firmly by means of the front and rear jacks, which are braced against the face and roof of the coal; this prevents the machine from moving while in operation.

The cutter, which is revolved by an endless chain, is fed forward, by means of rack and pinion wheels, to a depth of five or six feet, according to the size of the machine. The usual length of the cutter-bar is 39 and 42 inches. When the full depth has been reached the feed is thrown off, and by means of a reverse lever, the cutter-bar is withdrawn to its starting place. This completes the cut, and the machine is moved over the length of the cutter-bar used, and another cut is made in the same manner. This is continued until the entire width of the room has been under-cut, after which the machine is again loaded on the truck and taken into another room. These cuts are made on an average of from four to six minutes each.

The amount of coal under-cut, or the lineal feet face for each machine, depends upon the quality of the coal, and the skill of the men handling the machines. In some coal veins the machines have cut at the rate of 130 and 150 lineal feet face in ten hours to a depth of six feet. Twice

this amount can be cut if the machines are run on double shift.

As an adjunct to the mining machine just described, the electric drill, illustrated in Fig. 3, affords a means of driving holes at any angle and in any position.

The drill consists of a small electric motor hung in an upright frame having projections at the top and bottom, arranged with adjusting screws, by means of which it is fastened to the roof and floor of the mine. This is supported by a brace to stiffen and hold the frame rigidly while the drill is in operation. The motor is of the same type as that on their electric coal mining machine, and of a size to develop one-half h. p. It has a speed of 2,000 revolutions per minute, which is reduced by means of gearing to 100 revolutions at the feed bar. The motor is started and stopped with a simple switch, a rheostat not being necessary. The current is conveyed from the line to the drill by means of a small conductor cable. The drill can be handled by one man, and, being simple in construction, any man with ordinary intelligence can run it with a few hours' instruction.

The results of many months working have shown that by the use of the electric mining machine, a saving of from 25 to 33 per cent. can be had over hand mining with a considerable gain in marketable product, on account of the small amount taken out in the bearing-in.

To the gain in labor obtained by the mining machine, must be added the economy due to the electric haulage of the product below the surface. The Jeffrey Company have also devoted attention to this important feature and as a result have designed the electric mine locomotive, illustrated in Fig. 1. The frame of the car is built entirely of iron, thus giving it both strength and the weight required on the track for necessary traction. It is furnished with an electric motor of the same type and voltage as the mining machine, and has steel-tired wheels and axles.

Current is transmitted to the motor by means of a double trolley of four wheels, running on two conductors placed along the sides of the hauling entry, the same being made fast to the ribs of the entry. There is no rail or ground return. The armature shaft has a pinion and spur gear, direct to the axles. The motor is speeded to run eight miles per hour. The car is furnished with sand boxes and electric head lights and double brakes. The motorneer sits at one end of the car.

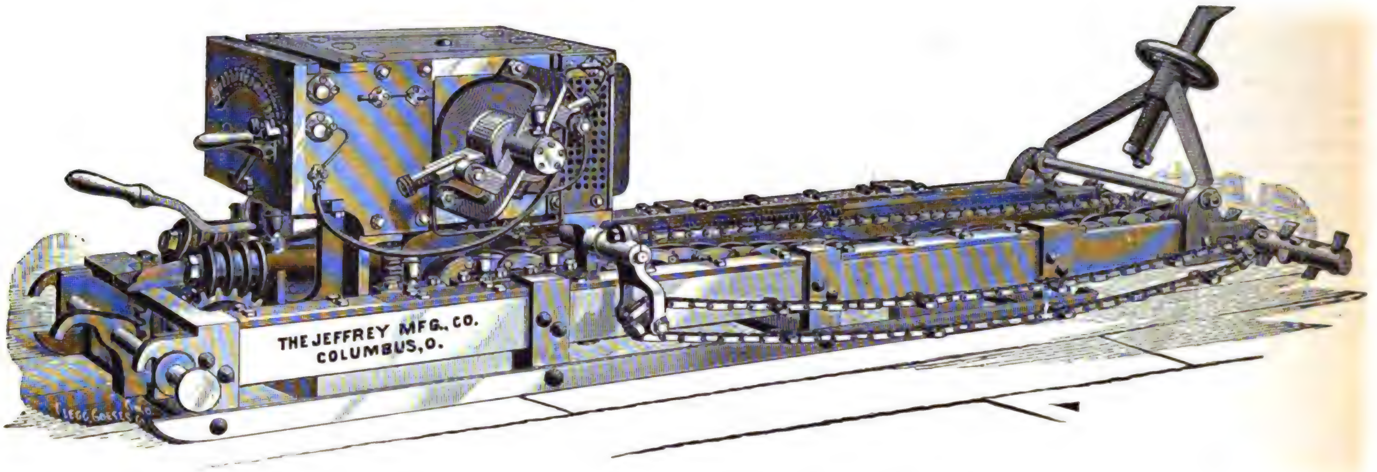

FIG. 2.—THE JEFFREY ELECTRIC COAL MINING MACHINE.

The size and capacity of the motor cars made thus far by the Jeffrey Company, have been of 20 h. p., weighing five tons on the rail. The motor car has worked on a grade against loads up to $4\frac{1}{2}$ per cent. The car is about 8 feet 6 inches long, by 46 inches high at the highest point.

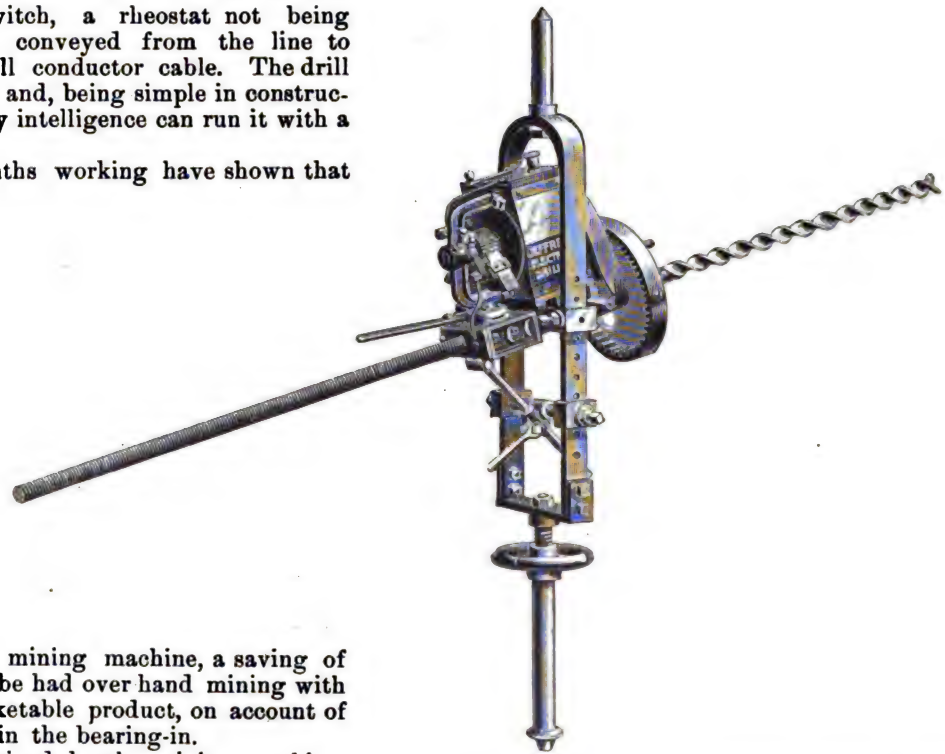

FIG. 3.—THE JEFFREY ELECTRIC MINING DRILL.

The installations made by the Jeffrey Company comprise the lighting and power equipment of quite a number of mines, including those of the Thurmond Coal Co., at Thurmond, W. Va.; the Sterling Mining Co., at Cannelton, Pa.; the Morris Coal Co., Brush Fork Mine, Hocking Valley, and a number of others. The success which has thus far attended the use of these installations will no doubt lead to their general appreciation.

"DUPLEX" RAILWAY TRACKS.

BY THOMAS H. GIBBON.

YOUR illustrations of the "Duplex" rail and lap joint system of railway construction in THE ELECTRICAL ENGINEER of Oct 29, have brought many prominent mechanical and electrical engineers, and contractors, to inspect our working model and to analyze this all-metal and simple system of railway construction; they have also brought many letters of inquiry from many states, respecting the cost of the system, and especially regarding the joint problem, and the contact of metal at the joints without wiring.

We, ourselves, are convinced that railway companies building with this system for electrical propulsion, save the expense of wiring at the joints, be it $100 or $400 per mile, which all other track systems entail to make this contact. No one doubts, who has inspected this system up to this writing (and they are numbered by scores), that a very great saving in labor in construction is effected; no one has yet doubted its absolute maintenance of gauge, and I do not think any practical man believes that there could be a low joint on this lap joint principle; that question has not once been mooted.

For the benefit of your readers, and also to answer the many inquiries, I have prepared a plan view of a joint chair, Fig. 2, showing how the girders of the rail are seated in the grooves of the chairs, and notches of the tie-bars, and all finally locked by the transverse wedge key; also, how the expansion and contraction of rails is provided for.

Of the many points of superiority which this system possesses, indicated in your article referred to above, none is more important than its "duplex" quality, and lap joint principle, for on that principle, and that only, can an absolutely jointless track be made or maintained, and upon this important feature in railway construction hangs very materially the financial prosperity of any railway company, and is the only means to absolutely make electricity the cheapest motive power that can be used, besides giving rapid transit and comfort to the traveling public.

It is a well recognized fact, that there can be no rapid transit where low and bad joints exist; it is also a recognized fact that bad joints cause rapid destruction to the rail, the motive power, the cars, and distress to the traveler. This is bad enough, but it is also recognized that electric propulsion is more destructive to the rail than any other motive power, be it steam, cable or horse—that the head of the rail is, as it were, under a planing machine, night and day, and must naturally wear out more rapidly than where the wheels only roll on the rails, as in cable or horse propulsion. This fact will sooner or later be more fully recognized, especially when two renewals of track, with all their attendant evils and expense, are to be made, instead of one, where horse or cable is used.

This is an important matter in finance, and no doubt will be seriously considered when it is more thoroughly understood that

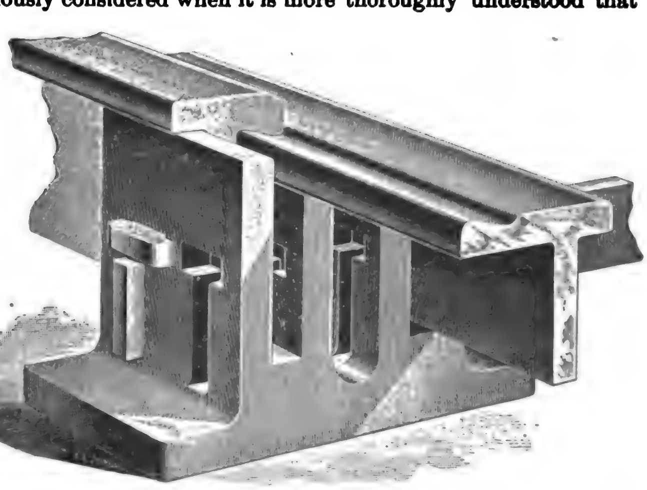

FIG. 1.—THE GIBBON "DUPLEX" RAIL CONSTRUCTION.

only about 9 pounds of head wear can be obtained from the heaviest section of rail rolled, whether side bearing, centre bearing, or grooved rail; it is sad to think that a 70 pound rail has only 9 pounds head wear (for the life of the rail is governed by the life of the head) and that 60 pounds is destined to be scrap. One renewal of such a road is equal to $1,500 per mile per annum for the life of the track, assuming that it will require eight years to wear this $\frac{7}{16}$ of an inch, and that is the utmost limit; or 9 pounds of metal of the head. This is exclusive of the repair account (of track only) which may be estimated at $300.00 per mile per annum.

The "Duplex" rail and lap joint system was designed to give longer life to the rail, by the removal of bad and low joints, by its lap joint principle. Its duplex character was designed so that either section of rail could be removed without discarding the whole, and also to give more lateral vertical stiffness to the track. The head section has all the wearing capacity of any other type, and only weighs about one-half of the whole rail; thus, at renewal, only 25 pounds per yard of scrap is made, instead of 60 pounds per yard with the single girder type, and furthermore the renewal can be made without much disturbance to the pavement.

The plan view of the joint chair shows the contact of the sides of the girders of the rail, with the inner faces of the grooves in the chairs, and also the upper and lower face of the wedge keys

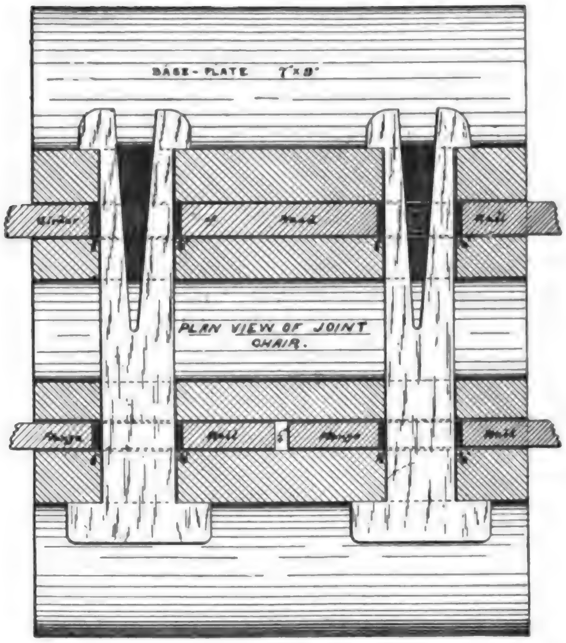

FIG. 2.—THE GIBBON "DUPLEX" RAIL CONSTRUCTION.

in contact with the top and bottom of the mortise in the girder of the rails.

The isometrical view of track at the joints, Fig. 1, shows the under face of the tram section resting upon, and therefore in contact with, the three vertical walls of the chairs; the under faces of the rails are in contact with the upper face of the solid flange rail. The under faces of the head rails are also resting upon, and therefore in contact with, the outer vertical wall of the chairs, thus making fifteen or more points of contact of metal the length of the joint chairs, instead of only two, when made by wire, the contact of which may be destroyed at any moment by the chemical action of the earth on the copper wire and steel rail. That there is a serious and detrimental action now taking place at the joint wires through the above named cause is already observed.

It is these and other kindred repeated outlays which are going to burden electricity as a cheap motive power in the future, and unless a great reduction can be made in track maintenance and renewals it is a question whether the profits are not largely swallowed up in renewal of tracks and cars.

What we have striven to accomplish in the Duplex system, and what is desired, is an imperishable track, rapid to construct, true to gauge at all times, the removal of low joints, ease of renewal and repairs, and smooth riding to the traveling public.

NEW YORK SUBWAY RENTALS.

The Board of Electrical Control met in the Mayor's office on Dec. 4. Mr. Lauterbach, for the Consolidated Subway Company, reported that the company had organized the Empire City Subway Company (Limited), and proposed, with the permission of the Board of Electrical Control, to release to it the work of constructing low-tension subways, at the same time holding itself liable to the board to do any of such work that the board might direct. The matter was referred to the corporation counsel for his opinion. The Mt. Morris Electric Light Company complained that the Consolidated Subway Company had failed to provide it with a duct in Duane street, although the Edison Company had been given one there. The Subway Company was directed to furnish the desired duct immediately.

The question of duct rentals was again discussed. The electric light companies claim that $1,000 per mile is too large a rental and are fighting against that charge in the courts. As a judicial decision in the case is expected this week, the board decided to take no action in the premises, and adjourned until Dec. 8, when the decision will guide their action.

ELECTROLYSIS OF ALUMINUM FLUORIDE.[1]

BY M. ADOLPHE MINET.

The author by continuing his researches on the electrolysis of the fused fluoride of aluminum, has been able to determine the composition of the electrolytic bath, which, for a given temperature and current density, yields the best results. The physical properties of the mixture of salts, and the relation between the current density and the constants of electrolysis, have also been found.

Composition of the Bath.—The bath is formed of a mixture of sodium chloride, and the double fluoride of aluminum and sodium. It is expressed by the chemical formula $6\ NaCl + Al_2\ Fl_6,\ 3\ NaFl$. Its fusing point is 675° C., and the temperature of vaporization 1035° C. Its electrical conductivity at the temperature $t°$ C. is expressed by the formula

$$C_t = 3.1\ [1 + 0.0022\ (t - 870°)].$$

For a current of 1,200 amperes the weight of the bath should be 20 kilogrammes, the current density should be 1 ampere per square centimetre of active surface of the positive electrode, and the voltage of the electrodes should be 5.5 volts.

The composition of the bath is maintained constant by adding a mixture of aluminum hydrate, oxyfluoride of aluminum, and the double fluoride of aluminum and sodium, by the action of which the aluminum disengaged at the positive electrode is reabsorbed by the mixed electrolyte.

Relation between the Current Density and the Electrolytic Constants.

Let V be the voltage applied to the electrodes, e the opposing electromotive force in volts due to the polarization of the electrolyte, R the resistance in ohms of the electrolyte, and C the current in amperes.

When the salts composing the bath are chemically pure, we may then distinguish three cases. In the first the current density is very small, and V and e are practically identical. If the temperature is constant, V is found proportional to C until the current density reaches an upper limit. This limit, when the temperature t is 870 degrees, varies between 0.02 and 0.03 ampere per square centimetre. Beyond this limit, and until the current density exceeds 1 ampere per square centimetre, the formula $V = e + R\ C$ holds, and the author gives several numerical results obtained from experiment and calculation. A few are appended below :—

$t = 852°$ C, $e = 2.15$, $R = 0.01$			$t = 890°$ C, $e = 2.40$, $R = 0.0044$			$t = 980°$ C, $e = 0.34$, $R = 0.0033$		
C	V Measured.	V Calculated.	C	V Measured.	V Calculated.	C	V Measured.	V Calculated.
130	3.50	3.45	196	3.26	3.26	572	4.25	4.23
245	4.60	4.60	885	6.18	6.29	1030	5.78	5.74

When the current density exceeds one ampere per square centimetre the value of V cannot be calculated as a function of C in any simple way. It rapidly attains a magnitude approximating to that required for an electric arc of 30 or 40 volts.

When the electrolyte is mixed with extraneous salts, such as those of iron or silicon, it is still true that while the current density lies between certain limits the decomposition takes place according to Sprague's law. The following numbers were obtained from experiments on a bath, from which the salts of iron and silicon were successivel y removed.

Iron present. $t = 810°$ C. $e = 0.75$ $R = 0.0093$.			Silicon present. $t = 840°$ C. $e = 1.37$ $R = 0.0089$.			Alumin'm salts only. $t = 870°$ C. $e = 2.15$ $R = 0.0085$.		
C	V Measured.	V Calculated.	C	V Measured.	V Calculated.	C	V Measured.	V Calculated.
75	1.45	1.45	65	1.95	1.95	100	3.00	3.75

TELEPHONY AT THE FRANKFORT EXHIBITION.

At the International Electrical Exhibition to be held next year at Frankfort, music is to play a novel and an important part. A large number of telephones will be fitted up in the buildings, by means of which visitors will be enabled to hear not only the concerts given in the Palmen-Garten, but also concerts at neighboring towns, Homburg, Soden, Wiesbaden, etc.; and it is even hoped to provide visitors with an opportunity of hearing the performances at the opera-houses of Mannheim and Munich.

1. *Comptes Rendus*, October 27, 1890.

THE CENTRAL STATION CITY PLANT AT ALLEGHENY CITY.

There is perhaps no plant in this country where so many lights are operated from such a small central station building as is the case at Allegheny City, Pa. The plant is owned by the city and it operates the alternating system exclusively, both incandescent and arc lights; and it is mainly for this reason that the company was enabled to run such a large number of lights from a comparatively small power-house.

The plant has a capacity of 4,500 incandescent and 540 arc lights. It was established last spring; and the contract for the installation of the electric light system was awarded to the Westinghouse Electric and Mfg. Co., after a severe competition.

The power house is a very handsome brick building situated near Braddock street and the tracks of the Pittsburgh, Fort Wayne and Chicago railroad. The roof of the building is graced by a beautiful tower from which the main wires are distributed. The boiler room is in the rear of the building containing a battery of six tubular boilers, each measuring 16 feet in length with a diameter of 66 inches. Slack coal is utilized as the fuel under the boilers and each of the latter are also fitted with a Roney patent stoker. The utility of this appliance has manifested itself in this plant to a very great extent from an economic point of view.

From the boiler room, a small door leads into the power house proper, the dimensions of which are 50 x 56 feet, and in this space the entire amount of the engines and dynamos for the operation of the complete plant are confined as follows: There are seven 160 h. p. Westinghouse compound engines, one 85 h. p. compound engine, two 15 h. p. automatic engines, three 1,500 light alternating current incandescent dynamos, two exciters and nine 60-light alternating current arc machines.

The switch board of both the incandescent and arc light occupies the greater portion of the north side wall in this room, containing all the switch board appliances used in connection with the Westinghouse system of electric lighting. The plant has been in operation since the fifteenth day of July last and since that time, there has never been any interruption in the service, either in the incandescent or arc light supply.

The working of the central station is superintended by Mr. David Hunter, Jr., and Mr. Maurice Coster acts as chief engineer.

The arc lights are used to light up the streets of the city. All the construction work in this direction was done by the North American Construction Co. The lights are distributed by mast arms and towers. Of the latter, the city has put up 53 with five lights on each and the rest of the lights are on mast arms.

The lights have given every satisfaction to the people of Allegheny City. Since the plant has been in operation the city has realized that the present capacity of the station is hardly sufficient to meet the demands of the entire place and an extension is already contemplated.

A LARGE ELECTRIC RAILWAY SYSTEM FOR BRIDGEPORT, CONN.

The Bridgeport Horse Railway Company, which has operated a line of horse cars since 1864, has sold out to a number of wealthy men. Among the purchasers are A. G. Yates, W. S. Kimball, the tobacco manufacturer; Frederick Cook, Arthur Luetchford, A. E. Perkins, Charles Everest, and J. N. Beckley, of Rochester, N. Y.; Edward M. Gibbs, of Norwich, Sherman H. Hubbard and Charles A. Hotchkiss, of Bridgeport. The purchase price was $350,000, about double the amount of the capital stock of the company. The purchasers of the line own the street railway lines in Rochester, Buffalo, Newark, N. J., Paterson, N. J., and other cities. They intend to extend the lines through more streets and to the suburbs of the city. When the work is completed there will be about twenty miles of the road in operation. Work on the improvements will be begun at once, and the tracks will be laid early next spring. The company intend to expend $1,500,000 in making improvements. The equipment of the road will be new throughout and electricity will be used as the motive power.

RESULTS WITH ELECTRIC ROADS IN ST. LOUIS.

Regarding the use of overhead electric wires for street car propulsion, Mr. E. V. Matlock, the supervisor of city lighting of St. Louis, writes as follows in reply to an inquiry addressed to the Mayor of St. Louis and referred to him :

The systems in use here are the Thomson-Houston, Sprague, and Short multiple systems. As far as known, no one has been seriously injured or killed by the electric railways. The people generally do not apprehend any danger from the electric railways, and the introduction of this method of transportation has almost doubled the traffic on those lines which are using it, and increased the speed of transportation about 100 per cent. over horses, and the general feeling of the residents along the lines of these electric railways, is one of great satisfaction with them.

Real estate in the western portion of the city has increased in value, in some cases over 300 per cent., and the general feeling is that it is a great improvement over other methods of travel. With a few exceptions, all the horse car lines have adopted, or are about to adopt, one of these systems, and the days of the horse car are numbered in this city.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.

Anonymous communications cannot be noticed.

The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.

In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.

Sketches and drawings for illustrations should be on separate pieces of paper.

All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

"ALIUM" INSTEAD OF "ALUMINUM."

[150.]—We have been much interested in the discussion which has been carried on through your paper and other electrical journals in reference to the proper spelling and pronunciation of the new word aluminium, and we understand that it has practically been decided to call it aluminum.

Prof. Thomson, in the course of a conversation the other day, suggested to us that while the matter was under consideration, it might be well to shorten the term and call it "alium." This impressed us as being a most excellent suggestion on account of its euphony, its ease of pronunciation, spelling, etc., and its similarity to the terms used to describe other metals, such as sodium, barium, calcium, cadmium, osmium, herbium, lithium and several others.

We have taken the responsibility of making this suggestion, although Prof. Thomson and ourselves realize fully that so great a change might involve considerable difficulty by giving rise to misunderstanding. Still, if this is to become a common metal, it seems to us that it should be about as easy to pronounce as gold, silver, tin, lead, iron or zinc.

EUROPEAN CORRESPONDENCE.

LONDON.

Fire at the London Electric Supply Corporation's Central Station.—Lighting of Madame Tussaud's.—Studying Electricity in the French Navy.—Telephones in France.—Supply of Electricity in Madrid.—Tenders for Spanish Coast Cable.

THE London Electric Supply Corporation's central station at the Grosvenor Gallery was burnt down on Saturday morning. This is a very serious matter, as the company is obliged to suspend business for the present. I am enabled to give the following statement from Mr. Ferranti about this station, and how the fire occurred.

Until recently the Grosvenor station was supplying the whole of the lights of the London Electric Supply Corporation. Owing to an injunction obtained by the neighbors, the company has been obliged to abandon it as a generating station and use it only for distributing the current supplied from Deptford. It was necessary to turn out the old machinery and install that for converting purposes, which would transform the high tension to the intermediate tension for supplying to the customers. It was imperative that the stopping of the generating plant should take place on Saturday night, and the transforming plant to be ready by as early an hour on Sunday as possible. This was partly done; the whole of the work was, of course, of a temporary nature.

The accident occurred at 6:30 on Saturday morning owing to the action of a lineman in plugging on a fresh set of converters. The man hesitated in putting in the plug, and a slight arc formed. He drew it back and broke the contact. The heated surfaces together with 5,000 volts pressure maintained the arc. It ran up the woodwork and set fire to the wookwork of the ceiling and burned out the whole place in the short space of twenty minutes. The lineman had ample opportunity of entirely stopping the damage, as a switch within a yard's distance would have broken the supply through the plug switch. There was still another safeguard, had he not been too frightened, and that was the safety switch at the end of the room which would have cut off the whole of the supply from Deptford. He could also have signalled for the current to be cut off. The ammeters and voltmeters at Deptford, however, showed that something was wrong in London, and the current was cut off.

Madame Tussaud's, the famous wax work exhibition, was lighted for the first time to-day by electricity.

The Great Northern Telegraph Company is about to lay a new direct cable between the west coast of Jutland and Calais.

By reason of the increasing importance of electricity to the navy, the minister for the French navy has just arranged for the instruction of the staffs of the arsenals in electrical science. He has decided that two foremen and two workmen, electricians, shall be sent to Paris from each French arsenal to study the working of the electric light. Lectures on the theory and practice of electricity will be given to naval officers at the observatory of Paris on and after the present date. They will last during four months and will be given every Thursday and Friday.

An agreement has been made between the government and the municipality of Argenteuil by which a telephonic line shall connect that city with Paris. M. Jules Roche, minister, has just submitted a decree to the President, which reduces the subscription to an overhead telephonic system to 150 francs in cases where the population does not exceed 25,000 inhabitants. This regulation comes into force on the first of January, 1891, in the case of towns already provided with a system, the number of whose subscribers does not exceed 100.

English and German companies in Madrid are now actively engaged in laying down wires for the supply of electric light in houses and business establishments. The German company has received orders for 11,000 lamps and the English company for, perhaps, as many as 6,000 lamps. The former can supply 22,000 lamps without using accumulators and 40,000 if they use Tudor's, as it is their intention to do. The streets in Madrid are now much broken up during the laying of the wires, and the public, though favorable to the electric light, shows some impatience with the present state of the streets. The English company have plenty of ground available on which they may enlarge their station for their alternating current supply. The German company, with their continuous current, have their cables only in the centre of the town and contemplate erecting two other stations outside. Both companies maintain the high price of 14d. to 15d. per unit.

Two tenders have been sent in for the laying of the cable between Spain and the African coast. One is from the India Rubber Company and the other from an Italian firm. Both tenders are in accordance with the conditions published by the government, but the chances are much in favor of the English proposal being accepted.

CHICAGO.

Amendments in the Chicago Club Constitution.—Marriage of George A. McKinlock.

AT the last meeting of the club, held at its rooms, 103 Adams street, on Monday evening, December 1st, the following amendments to the constitution and by-laws were adopted:

Changing Article III, Section 1, to read as follows: Resident members shall pay an entrance fee of Fifty dollars, and annual dues of Forty dollars.

Article III, Section 2—Non-resident members shall pay annual dues of Twenty dollars.

Article III, Section 3—Non-resident members becoming resident members, must pay the entrance fee.

Article III, Section 4—The financial year of the club shall commence on the first day of April of each year.

Article IV, Section 2—The president or one of the vice-presidents shall preside at all meetings of the club; in their absence a temporary presiding officer may be elected.

Article IV, Section 6—At all meetings of the board of managers the chairman shall preside; in his absence a temporary presiding officer may be elected.

Article IV, Section 6—To be numbered Section 7.

Article VII, Section 1—Resident members only are entitled to vote at any regular or special meetings of the club; and they must vote in person.

Article VII, Section 2—No member who is in arrears for dues shall be entitled to vote at any meeting or election.

Mr. E. F. Browne then read a highly instructive and carefully compiled paper on "Electricity in Mines and the Proposed Mining and Electrical Display at the World's Fair." A lively discussion ensued which was participated in by Messrs. Bain, Badt, Goodman, Armstrong, Cutter and Browne.

Mr. George A. McKinlock, the popular and genial treasurer of the Central Electric Company, was married Tuesday evening, December 2nd, to Miss Marion Rappleye, at the residence of Mr. Rappleye, No. 3,636 Prairie avenue. The ceremony was conducted by Bishop Cheney, and was solely a family affair, none but the members of the two families and immediate relatives being present. After the ceremony, Mr. and Mrs. McKinlock left for New York, from which city they sailed on Saturday on the steamship "Etruria" for a year's tour in Europe. I desire to congratulate them and to unite with their many friends in wishing them every happiness. Messrs. W. L. Candee, Geo. Manson and Durant Cheever, of the Okonite Co., have sent them a most beautiful and

useful present in the shape of a complete set of silver table ware, consisting of eighty-nine pieces, with monogram on each, in an oak case. The staff in the office of the Central Electric Co. have also remembered Mr. McKinlock and presented a very handsome field glass, which he will no doubt use with much pleasure during his sojourn abroad.

CHICAGO, Dec. 5th, 1890.

BOSTON.

Rules for Motor Men.—Work for Inspector Flanders.—The Meigs Elevated Road.

GENERAL MANAGER MONKS, of the West End Railway, has issued the following order to motor men on electric cars:

"You are hereby notified that you must not hold conversation with any passenger while on duty on your car. If passengers wish to engage in conversation with you, tell them, politely, that you are not allowed to talk with them, as your time and attention must be fully occupied in the careful operation of the car."

Since Mr. B. S. Flanders has been appointed and confirmed inspector of electric wires, there has been some curiosity on the part of the fire commissioners to know whether the new ordinance took the control of the fire-alarm telegraph out of their hands, and placed it in the hands of the new inspector. It is the opinion of the corporation counsel that the wires and apparatus of the fire-alarm system should be under the control of Mr. Flanders, but that considerable time will have to elapse before Inspector Flanders will be able to arrange all the details. The question is a nice one, and exactly where the dividing line will come in it is impossible yet to tell.

At a meeting of the board of aldermen, an order was passed that $12,556.77 be transferred from the appropriation for fire department, the said sum to constitute an appropriation for the department for the inspection of wires.

The committee on railroads reported leave to withdraw on the petition of the Meigs Elevated Railroad Co. for location on certain streets.

BOSTON, Dec. 6, 1890.

PITTSBURGH.

Progress in Electric Railroads.—Lighting the Public Buildings.—Track Lighting for Steam Railroads.

THE Knoxville Incline Company, of this city, is erecting an electric light plant for the purpose of illuminating the entire track of the incline from Mount Oliver down the hill to the foot of South Thirteenth street. The plant will be in operation within a few weeks, and it will not only illuminate the hillside very brilliantly, but it will also be a great blessing to the people who are now obliged to climb the hill during the night in utter darkness. The company hopes also to avoid accidents by the lighted condition of its line.

A number of the cars of the Duquesne Traction Company have now arrived in this city, and they are being equipped with electric motors at the company's power house. It is expected that the first trip will be made during Christmas week.

The Cambria Iron Company is now engaged in the manufacture of the street rails for the tracks of the Troy Hill Electric Street Railway line in Allegheny City. The poles are now being put up, and as soon as the rails arrive the roadbed will be laid as quickly as possible. The management of the railway hope to have the cars running in two months at the latest.

The secretary of the treasury has recommended the appropriation of $15,000 for an electric plant to be utilized in the illumination of the new Pittsburgh Custom House and the Post Office building. In addition to that he has also recommended the appropriation of $185,000 for an electric lighting plant for the new public building in Allegheny City.

The stockholders of the Second Avenue Electric Street Railway Company held their annual meeting a few days ago. They elected a new board of directors and officers for the ensuing year, and they also received the report of the treasurer. The latter showed that the company had earned during the first nine months of the year $23,227.65 net.

One of the most practical schemes for the utilization of electric lighting is now being introduced by the Pennsylvania Railroad Company. In considering ways and means towards the alleviation and decrease of accidents to life and property on their lines, the management has decided to establish electric lighting stations at such places along their system of tracks, where the traffic is so large as to be of constant danger to the traveling public and the employés of the company. The first trial is now being made from Frankford Creek to Torresdale, a distance of 11 miles. If this experiment proves satisfactory the company intends to light up the entire track from Philadelphia to New York City.

PITTSBURGH, Dec. 5, 1890.

FINANCIAL MARKET.

QUOTATIONS ON ELECTRICAL STOCKS.

BURNING UP OF AN EDISON ORE CONCENTRATION PLANT.

A special despatch from Marquette, Mich., of Dec. 4, says:—"The experimental station erected by Thomas A. Edison at Humboldt, thirty miles west of Marquette, for the purpose of concentrating low grade iron ores by electricity was destroyed by fire last night. The fire began in the engine house. The building was valued at about $7,000 and contained two dynamos and much valuable machinery, all of which is ruined, making the total loss not less than $12,000. There was $5,000 insurance.

"The station was established two years ago. Although no information was given to the public regarding the success of the experiments, it is generally understood that Edison's process was proving successful. At the time of the fire preparations were being made to ship a car load of ore which had been raised from 50 to 71½ per cent."

A NEW TELEPHONE EXCHANGE FOR ALBANY.

The Hudson River Telephone Co. has asked the permission of the Albany City Council to put its wires in that city underground. Mr. A. B. Uline, general manager, says that the company are negotiating for a site on which a handsome granite fire-proof building will be erected for the telephone exchange. In all the parts of the city where the wires and poles look unsightly and are in the way, the company desires to remove the poles and lay the wires underground. This improvement will probably be made in that part of the city bounded by North Ferry street and the Lumber district on the north, Second avenue on the south, Swan or Lark streets on the west and the river. The conduits will be laid through the streets included within these limits, and communication with them will be through manholes at every intersection of streets. The conduits will contain about 20 lead covered cables, each cable containing 50 pairs of wires.

The company desires to obtain the permission from the Common Council as soon as possible, but will probably not begin laying the conduits until next spring, as pavements could not be relaid properly during the winter.

MR. JOHN N. STEWART, the new president of the Ohio State Tramway Association, is an old military telegrapher, who was assigned to duty in the vicinity of Washington, D. C. After the war, he closed the circuit telegraphically with the golden spike and silver mallet when the great railroads across the continent made their junction at Promontory Mountain. Since then he has been prominent in a number of enterprises.

LIGHT AND POWER FOR RAILWAY SHOPS.—The order recently placed by the Union Pacific system, for lighting the shops of the Denver Union Railway & Terminal Co., at Jersey, Col., with the Western Isolated Lighting Department of the Thomson-Houston Electric Co., comprises two 500 light dynamos and other appliances, including wiring, necessary to operate 1,100 incandescent lamps; also a 600 light generator which will be used in connection with an electric motor for running a transfer table.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The next meeting of the Institute, to be held at the house of the society, 12 West 31st street, at 8 p. m., on Tuesday, Dec. 16, promises to be very interesting. Mr. A. E. Kennelly will present a note on "Inductance and its Proposed Unit, the Henry," and Mr. Emile Berliner will read a paper on "The Perfected Gramophone," with illustrations and experiments. The machine will be exhibited, on this occasion, for the first time in New York City. Members are invited to bring ladies.

NEW YORK ELECTRICAL SOCIETY.

This society is doing admirable work, and its next meeting, at 8 P. M. on Wednesday, Dec. 10, promises to keep up the high standard. A paper is to be read by Mr. E. P. Thompson, the well-known patent expert and attorney, on "How to Make Great Inventions; or, Inventing as a Science and an Art." The meeting is to be held at the Socy. of Mech. Engineers, 12 West 31st Street, and as a general invitation is extended, a very full house may be expected. The subject is one of the utmost interest and importance.

DINNER AT THE NEW YORK ELECTRIC CLUB.

The December meeting of the club was celebrated by a dinner, for which no fewer than 75 covers were laid. An excellent dinner was served by Club Steward Stadler. After dinner, speeches were made by Mr. Erastus Wiman, Mr. Joseph Howard, the famous newspaper correspondent, now of the New York *Press;* Capt. Zalinski, who bade the club farewell, as he was leaving for duty on the Pacific Slope; Mr. T. C. Martin, Mr. Foster Coates, of the *Mail and Express;* Mr. P. H. Alexander, and Mr. Adams, of Boston. Mr. Howard was also prevailed upon to tell how, in his early days, while attending to the movements of the Prince of Wales in Canada, he had telegraphed large blocks of Biblical genealogy to New York, in order to prevent a rival from getting the use of the wires. Mr. F. Z. Maguire also enlivened the evening by playing an original composition, "Valse Electrique," on the piano. The festivities were kept up until nearly midnight, and a most delightful and successful evening was spent.

THE CITIZENS' ELECTRIC CO.'S BALL IN BROOKLYN.

Between 200 and 300 people, officers and employés of the Citizens' Electric Illuminating Co, of Brooklyn, and their friends, gathered at Saengerbund Hall, Brooklyn, last Friday, and "tripped the light fantastic" to the music of the latest popular airs, the occasion being the fourth annual ball of the Employés Mutual Benefit Association. Dancing commenced at 10:30 o'clock and continued until a late hour, supper being served during intermission. The proceeds of the ball will be added to the fund already in the treasury of the Benefit Association. Among those present were J. Supple, B. Rush, E. Reynolds, J. R. Barefield, E. F. Peck, T. H. Brady, of Brady mast arm fame, E. D. Cook, Supt. of the Brooklyn Edison Co., W. H. Barstow, Gen. Mgr. of the Brooklyn Edison Co., John Birkett, W. H. Bowne, Chief Engineer of the Citizens' Co., James Ferguson, Supt. of the Municipal Electric Light Co. of Brooklyn, Frank Mason, Supt. of Police Telegraph, and Hon. John Delmar. To Mr. Reynolds, Secretary of the Association, great praise is due, on account of his untiring efforts to make this affair the deserved success that it was. Everything went smoothly, evincing careful forethought and the best of management. THE ELECTRICAL ENGINEER speaks of the ball's brilliant success from personal observation.

AMERICAN CONTROL OF THE NEW PACIFIC CABLE.

There are strong arguments for participation by the United States Government, says the Worcester, Mass., *Gazette*, in the plans for a trans-Pacific telegraph cable to connect the coast of the continent with Samoa, Hawaii, and Australia. The President has just urged Congress, in his Message, to take action to prevent the mail-carrying Pacific steamships from changing the American terminus of their voyages from Australia and the Pacific islands from San Francisco to Vancouver, in British Columbia. Senator John H. Mitchell, of Oregon, now urges Congress to take a hand in the plans for a cable under the Pacific, and predicts that the cable will certainly be soon laid, and that if the United States holds aloof from the project, the cable will be laid under British and Canadian auspices, and its eastern terminus will be in British Columbia. Men of affairs in the Northwest have special reasons for knowing and appreciating the dangers of allowing the ports of British Columbia to gain steamship advantages over the United States Pacific ports. They and the President make these dangers clear to the people of the rest of the country. They have a strong line of argument in the evident social, political, commercial and military value there would be in a Pacific cable landing within United States territory.

REPORTS OF COMPANIES.

STOCKS AND BONDS.

HANNIBAL, MO.—A special popular vote was taken on Nov. 25, on the proposition to issue bonds to the amount of $20,000 to increase the power of the city electric light plant and to put in an incandescent plant. The proposition was carried, with the necessary two-thirds majority and 144 votes to spare.

MACKAY'S PURCHASE OF THE BANKERS' AND MERCHANTS' COMPANY.

A deed was recorded at Washington, on Nov. 28, by which W. N. Armstrong, of New York, as referee, conveyed for a consideration of $890,000 to John W. Mackay, of Virginia City, Nev., all the rights, franchises and privileges of the Bankers' and Merchants' Telegraph Company, the Bankers' and Merchants' Telegraph Company of New Jersey, the Bankers' and Merchants' Telegraph Company of Pennsylvania, and the Bankers' and Merchants' Telegraph Company of Indiana, including the lines of the company from Washington to New York.

OUTPUT OF AMERICAN BELL TELEPHONE INSTRUMENTS.

The Bell Telephone Company makes the following favorable statement of instruments for the month ended the 20th of November:

Month Nov. 20.	1890.	1889.	Increase.
Shipments	5,318	3,763	1,555
Returned	2,926	2,929	*3
Net output	2,392	834	1,558
Since Dec. 20.	1889-90.	1888-9.	
Shipments	59,105	52,157	6,948
Returned	25,241	22,827	2,414
Net output	33,864	29,330	4,534
Instruments in use Nov. 20	478,725	440,871	37,854

PROPOSED ISSUANCE OF WESTINGHOUSE PREFERRED STOCK.

With regard to the announced intention of the Westinghouse Electric and Manufacturing Co. to issue $3,000,000 of preferred stock, the directors of the company have made an official statement, in which they say: "The difficulty in raising new money for carrying on the increasing business of the company and carrying terms has, owing to the stringency in the money market, been very considerable, and it has been finally decided, after a long discussion, that the only practical manner in which to provide for the wants of the company is to exercise the power conferred by its charter of issuing preferred shares, and a meeting of the stockholders has been called for this purpose. A proposition will be submitted to the stockholders to authorize the directors to issue the remaining $2,000,000 of authorized increase, and to convert a total of $3,000,000 of the $10,000,000 into preferred stock, the preferred stock to be entitled to a dividend of 6 per cent. in preference to the common stock, and this dividend to be accumulative, and these shares to share equally in the profits when the dividends are more than 6 per cent. on both the common and preferred stock. The management expects to have its subscriptions completed by the time of the meeting to enable the company to carry on its business in a comfortable manner. The recommendation to create preferred stock was adopted unanimously after full discussion and after consultation with parties having a considerable interest in the company. It is believed that these shares will find a ready market as soon as people are in a position to make investments, and that the extinguishment of the debt of the company by the issue of the preferred shares will at once advance all of the shares of the company to the position they should occupy by reason of the very large business which the company is doing. These preferred shares are to be sold at par, and it is proposed to have the interest payable July and January."

A stockholders' meeting was called for this Wednesday, Dec. 10.

THE ELECTRIC CAR CURE FOR RHEUMATISM.

One of the latest crazes in St. Louis is that of riding upon the electric cars to cure rheumatism, and hundreds of victims of the dreaded affliction who have borne their sufferings in silence are now eagerly seeking for information and testing the new cure. "It is amusing to see passengers on our line eyeing each other and whispering to companions about the new cure for rheumatism," remarked a Union Depot Line conductor, laughingly. "If a man, woman or child boards a car with a crutch or cane you can hear whispers to the effect that there is a rheumatic patient out to test the new cure."

LEGAL NOTES.

PIKE ELECTRIC CO. vs. RICHARDSON DRUG CO.—CLAIM FOR WIRING DONE.

The action was brought to recover a reasonable value for labor and material used in putting in an electric light plant in the drug company's house on the corner of Fourth street and Clark avenue, St. Louis. Before the plant was completed the house burned, and the Electric Company sued for what they claimed was due them under the contract. The plaintiff company obtained a judgment for $1,700 in the Circuit Court, but on appeal, the judgment has been reversed and the case remanded.

HYDE PARK DIST. TEL. & ELEC. CO. vs. CITY OF CHICAGO.—POLE LINE PRIVILEGES.

The Hyde Park District Telegraph and Electric Company has secured an injunction from Judge Horton restraining the city of Chicago from removing complainant's telegraph poles and interfering with the placing of wires over the territory formerly known as Hyde Park. In February, 1889, the trustees of Hyde Park granted a franchise to complainant to erect poles and lay wires in any street and alley in Hyde Park on getting consent from a majority of property owners abutting such route. When the village was annexed to Chicago the telegraph company asked the Commissioner of Public Works for authority to erect new poles and this was denied, as the city ordinance requires all wires to be located underground. The company, however, insists that it has a right to string wires on new poles under the ordinance passed by the village trustees. The city will move to dissolve the injunction.

A DECISION AGAINST THE SINGLE TROLLEY IN OHIO.

A decision was rendered in the general term of the Superior Court at Cincinnati, on December 2, against the use of the single trolley system on the Mount Auburn electric road. The Mount Auburn Co. has given notice of an appeal to the Supreme Court of the State.

BRUSH ELECTRIC CO. vs. SPRAGUE ELECTRIC RAILWAY AND MOTOR CO.

In the suit of the Brush Electric Company against the Sprague Electric Railway and Motor Company for alleged infringement of patent, the defendent company has filed an answer in the office of the Clerk of the United States Circuit Court. In this answer all the allegations in the bill of complaint are generally denied. It is also averred in the answer that the letters-patent granted to Charles F. Brush are void and of no effect, principally because the improvements or inventions claimed by him are described in previous letters-patent granted in this country and Great Britain prior to his alleged invention, and because, it is asserted, Elihu Thomson, and not Brush, was the original inventor of the alleged improvements.

A TELEPHONE COMPANY'S REFUSAL TO PAY STATE TAXES.

Vice-Chancellor Bird, of New Jersey, has refused the State's application for an injunction to restrain the Pennsylvania Telephone Company from doing business in New Jersey. The application was made because the company refused to pay $3,648 taxes, which they said was on business done partly in this State and partly in adjoining States, and therefore came properly under the head of Inter-State commerce. The company's line runs from Scranton, Pa., to New York, passing through New Jersey. In refusing the injunction, the Vice-Chancellor, however, adds, that he does not set aside the assessment, as this is a proper subject not for chancery, but for a court of law.

INTERSTATE TEL. CO. vs. B. &O. TEL. CO.—AN ACCOUNTING REQUIRED.

The Interstate Telegraph Company has filed a bill in the United States Court, at Baltimore, against the B. and O. Railroad and the B. and O. Telegraph Company.

The bill alleges that the complainant recovered recently a judgment against the Baltimore and Ohio Telegraph Company for $25,000 and costs, which it has been unable to collect, and prays for a receiver of the B. and O. Telegraph Company, and that the railroad may be required to account to the creditors of the telegraph company for so much of the $4,000,000 received by it from the Western Union Telegraph Company as may be necessary to satisfy the claims of the complainant and all other creditors who may come into the case.

LEGISLATION IN BEHALF OF TELEGRAPH OPERATORS.

The telegraph operators throughout the State of Georgia are endorsing the bill introduced in the State House of Representatives on November 26, by Representative Boifeuillet. The following is a testimonial handed to him on Nov. 27, upon his arrival in Macon :—

"We, the undersigned telegraph operators of Macon and vicinity, hasten to express our utmost solicitude for the speedy passage of the bill introduced by you in the house to-day, prohibiting railroad companies in Georgia from employing any telegraph operator under eighteen years of age, and who has not had at least one year's experience as an operator. Speaking from experience, we are in full sympathy with the bill.

"It is an indisputable fact that nine-tenths of the terrible railroad disasters attributable to telegraph operators in America are directly traceable to inexperienced and grossly ignorant and incompetent boy operators. And we hold that travel is seriously imperiled on any road where such service is permissible.

"In thus tendering our endorsement of your measure, we faintly voice the earnest sentiment of the fraternity, not alone in Georgia, but throughout the United States. The names hereto appended were all subscribed within an hour's time."

This is followed by a long list of names.

WESTERN UNION OBJECTIONS TO TELEPHONE WIRES.

The Western Union Telegraph Company has refused to allow the New England Telephone Company to string its wires alongside the Boston & Maine tracks in Danvers. An effort is now being made to get the needed permits from those who own the land next to the railroad. This will probably be successful, and the difficulty removed.

MUNICIPAL LIGHTING PROPOSED FOR WHEELING, W. VA.

A brisk discussion is going on at Wheeling, W. Va., as to a municipal lighting plant, and all the old arguments from Dunkirk, Ypsilanti, and elsewhere, to show that municipal plants are economical, are being used as though they had never been exploded and shown to be utterly wrong, deriving fallacious conclusions from widely inaccurate figures. The Wheeling Electrical Co. stands ready to furnish lights at $75 or $80 a year, and the city council will be level headed if it closes a contract at that figure.

THE PRESIDENT ON GOVERNMENT TELEGRAPHS.

The following passage from the message of President Harrison to Congress relates to the use of the telegraph by the government: "The use of the telegraph by the post-office department as a means for the rapid transmission of written communications is, I believe, upon proper terms, quite desirable. The government does not own or operate the railroads, and it should not, I think, own or operate the telegraph lines. It does, however, seem to be quite practicable for the government to contract with the telegraph companies, as it does with the railroad companies, to carry at specified rates such communications as the sender may designate for this method of transmission. I recommend that such legislation be enacted as will enable the post-office department fairly to test by experiment the advantage of such a use of the telegraph."

WORCESTER GAS AND ELECTRIC COS. NOT ALLOWED TO CONSOLIDATE.

The petition of the Worcester Gas Light Co. for authority to engage in the business of generating and furnishing electricity for light and power, which means a consolidation of that company with the Electric Light Co., has been dismissed by the State board of gas and electric light commissioners. The commissioners state in brief that there is no call for a consolidation of the two companies, and that the public would derive no benefit from such a consolidation.

EDISON LAMP PRODUCTION.

It is stated by the Newark *Call* that the new buildings which have been added to the Harrison Lamp Works of the Edison General Electric Co. are completed and will be ready for occupancy in about two weeks. Two hundred additional hands will be employed, and the output of lamps, stimulated actively by the recent reduction in price, will be increased to 25,000 per day.

A CITY ELECTRICAL INSPECTOR FOR NEW ORLEANS.

The city authorities of New Orleans have lately been busy considering questions of pole lines and the insulation of wires. The matter of appointing a city electrician has also been discussed, and the fire and lighting committee proposes that the official to hold this position shall draw a salary of $1,200.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DEC. 2, 1890.

Alarms and Signals ;—

Electric Clock-Alarm, M. W. Tiedemann, 441,906. Filed June 27, 1889.

Alarm clock has one of its legs removably arranged in an open circuit and a key rotating with the alarm mechanism, together with an electric connection with which the key makes contact closing the circuit and sounding an alarm.

High-Water Alarm, I. H. Simpson, 441,962. Filed May 19, 1890.

For tanks and water-towers. A discharge pipe placed at high-water mark discharges into a spring-supported bucket which actuates an electric circuit-closer operating an alarm.

Annunciator, F. E. Fisher, 442,029. Filed July 7, 1890.

An annunciator for indicating either of two words or numbers as "in" or "out." Mechanical device for amplifying the movement of a pointer beyond a range conveniently obtained by the electro-magnet.

Conductors, Conduits and Insulators :—

Machine for Covering Wires, Cables, etc., and for Making Tubing and Cord, V. Royle and J. Royle, 441, 808. Filed Aug. 30, 1890.

Third claim follows :

The combination with the head of a press for covering wires, cables, or other bodies or making tubing of a die laterally adjustable relatively to the core, and a core which is adjustable in an axial line or lengthwise relatively to said die, substantially as herein set forth.

Conduit for Electric Conductors, E. T. Greenfield, 441,837. Filed Dec. 14, 1889.

The tube or conduit has a body of insulating material and a continuous protecting skin or envelope of a less inflamable material, which latter may be metallic, if desirable.

Attaching Device for Electric Conductors, E. T. Greenfield, 441,838. Filed Mar. 3, 1890.

A flexible metal strip having a hole about midway of its length for securing it to a wall or ceiling by a nail or screw, and an eye at one end and a tongue at the other to serve as a lock or fastening when the strip is bent around a tube or conduit.

Process of Impregnating Porous Bodies, E. T. Greenfield and J. Nagel, 441,839. Filed May 9, 1890.

Method of treating fibrous, porous or cellular bodies, applicable for use in electrical tubes or conduits.

Underground Conduit for Electric Wires, E. T. Greenfield, 441,840. Filed May 27, 1880.

A conduit system for underground wires embracing man-holes, hand-holes, and junction-boxes for distribution. Conduit consists of a trough, preferably rectangular and made of wood treated with waterproofing and preservative material ; wire-ways formed within the trough of compound tubes of high insulating properties ; the tubes are held in position at certain distances apart by uprights attached to the base-board of the trough, the tubes are supported away from the bottom of the trough, and when desired in successive tiers, by cross pieces, the ends of which lie in grooves in the opposite side of the trough. An insulating material in a fluid state is poured into the trough and allowed to harden after the wire-ways or tubes are fixed in position.

Process of Working High-Boiling Hydrocarbons for Impregnating Purposes, E. T. Greenfield and J. Nagel, 441,870. Filed Feb 25, 1890.

Applicable to tubes or conduits for electric wires. Consists in maintaining the hydrocarbons in a liquid condition by heat and adding from time to time a lower boiling hydrocarbon or equivalent to supply the volatile matters evaporated.

Electric Wire-Coupling, W. E. Banta, 441,919. Filed June 11, 1890.

Consists in a series of rings surrounding the jointing wires and adapted to retain the full strength of the metal composing them and to bite the harder upon the jointing wires the greater the stress : the rings may be connected together by a bar secured to them along the line of the jointing bars.

Dynamos and Motors :—

Regulator for Electric Motors, W. E. Hyer, 441,665. Filed Oct. 10, 1889.

A mechanical device located between the load and the motor and operated directly by the former. The pulley transmitting the power from the motor is connected with the motor shaft through a coil spring and a sliding block feathered on the shaft. The sliding block has a cam-surface which bears against a similar cam-surface on the pulley. The rotation of the pulley is opposed by the spring, the amount of lost motion allowed by the spring, through the effect of the load, determining the distance which the sliding block moves longitudinally on the shaft. The movement of the sliding block may be utilized in any way desirable, as for example, switching in or out resistance, to effect the regulation.

Brush-Holder for Electric Motors or Dynamos, W. S. Patterson, 441,695. Filed Aug. 20, 1890.

Design and construction of yoke and brush holder. Invention consists in details of construction.

Dynamo-Electric Machine, W. K. Freeman, 441,793. Filed Sept. 20, 1890.

Design and construction for simplifying and improving alternate current dynamos, consists chiefly in details of the armature construction.

Regulator for Dynamo-Electric Machines, W. K. Freeman, 441,794. Filed Sept. 20, 1890.

Hand regulation. Horn-shaped pole-pieces of field magnets, embracing the armature, are pivoted so that they may be expanded away from, or contracted towards, the periphery of the armature by means of a screw and hand-wheel.

Motor-Regulator, D. Pepper, Jr., 441,807. Filed Oct. 1, 1890.

First claim follows :

The combination of a resistance-box connected at one end with a circuit, a switch arranged as specified to complete the circuit through said box, and by progressive movement cut out resistance until at the end thereof the box is cut out, a second switch arranged to connect with the circuit as the first switch severs connection with the resistance-box, and automatic means for moving said second switch over the resistance-box in the circuit, all substantially as and for the purpose specified.

Electro Motor, H. Groswith, 441,953. Filed Aug. 13, 1889.

Reversing mechanism for electric motor, for changing the direction of rotation of the armature ; applicable to motors of the class having two sets of coils upon the armature and two commutators.

Method of Operating Electric Motors, H. Groswith, 441,954. Filed Mar. 5, 1890.

Claim 2 follows :

An electric motor having a set of field-coils, armature coils, and commutator in one circuit, a duplicate set of elements, a common external connection to one brush of each commutator, and a pair of contacts or binding-posts connected respectively to the two other brushes for external connection.

Lamps and Appurtenances :

Incandescent Lamp Fixture, F. Lewis, 441,877. Filed Aug. 9, 1890.

Pendant attachments to the key of incandescent electric lamps.

Electric Arc Lamp, T. P. C. Crampton, 442,018. Filed July 14, 1890.

Claim 1 follows :

In an electric arc lamp, the combination with a pair of differential solenoids and adjustable stops, of an upper carbon-holding tube, having at its upper end a tubular iron core sliding in the solenoids and provided at its lower end with spring-clutch jaws acted on by the adjustable stops to release the carbon, substantially as described.

Guard for Incandescent Electric Light Globe, J. Mino, 442,071. Filed Feb. 27, 1890.

A wire guard similar to that employed upon lanterns.

Galvanic and Thermo Electric Batteries :—

Galvanic Battery, A. H. Hoy, 441,843. Filed May 26, 1890.

Construction of cell and elements specially applicable to dry batteries.

Galvanic Battery, C. G. de Peralta, 441,967. Filed May 23, 1890.

Zinc and carbon electrodes separated by blocks of insulating material and bound together : a metallic containing vessel, and a paste containing an active and a deliquescent material surrounding the electrodes.

Miscellaneous :—

Electro-Thermostatic Valve, L. Bell and F. H. Root, 441,817. Filed July 5, 1890.

Claim 1 follows :

The combination, with a fluid-controlling valve, of a volatile-fluid chamber having a diaphragm connected to the valve and adapted to operate the latter, and an electric circuit including a resistance for heating the volatile fluid, and a circuit-closer, substantially as described.

Electric Line-Hook, F. M. Locke and J. Lapp, 441,849. Filed Sept. 8, 1890.

The opening through the hook is large enough to permit a knot or splice to pass through it freely ; arms on each side of the hook to which the wire may be tied ; the shank of the hook is flattened or cut away on one side, the more readily to permit pouring melted sulphur into the insulator around the shank after the insertion of the hook.

Apparatus for Electroplating, W. J. Possons, 441,892. Filed Oct. 18, 1889.

Devices for facilitating the manipulation of articles to be plated ; a combination of circuit-closers and the clamping devices to hold the work so arranged that the current used for electroplating will be shunted around an empty clamp while the circuit through the filled clamps will be maintained intact.

Apparatus for Electroplating, W. J. Possons, 441,893. Filed Oct. 21, 1889.

Devices for reducing the cost of manipulating electric light carbons and other similar articles while electroplating them, through the substitution of machine work for hand labor. In connection with plating tanks a system of track-ways, trucks and clamps for handling the work to be electroplated.

Apparatus for Electroplating Carbons or Other Articles, W. J. Possons, 441,894. Filed Oct. 17, 1889.

Similar in purpose to the above. Apparatus for charging comprises a series of tubular holders and an adjustable hinged rack constructed with grooves for holding and guiding the articles to the holders.

Rheostat, T. K. Ames, 441,918. Filed Sept. 15, 1890.

Claim 1 follows :

The combination, in a regulating-switch, of a spool and a resistance-coil wound thereupon, one head of the spool carrying the resistance-terminals and the other head of the spool constituting the base or back plate whereby the switch is secured to a wall or other surface, substantially as specified.

Electrotype, W. T. Barnum, 441,920. Filed May 5, 1890.

Design and construction of electrotype block.

Thermal Out-Out, D. J. Cartwright, 441,933. Filed April 26, 1890.

Consists in the arrangement, between the terminals of a fusible wire of a cut-out, of plates of an infusible and non-conducting material, through or around which the fusible wire passes in a zigzag direction. Object: to interrupt the arc that may be formed upon the melting of a fused wire. Attains the same object by the alternative method of making perforations in plates of non-conducting materials interposed between the terminals of the fused wire and through which perforations the fused wire passes, bars or plates of infusible or non-conducting material being pivoted to the fixed plates through which the wire passes, above each perforation, so as to fall by their own weight and close the perforation when the fused wire has melted.

Electrical Indicating Apparatus for Linear Measure, J. Rapieff, 441,972. Filed Mar. 13, 1889.

Claim 1 follows:

The combination, in a range-finding instrument, of two telescopes or alidades having a linear movement with relation to each other, one or both thereof bearing electric contacts, conductors parallel with the path of movement of the telescopes upon which the said contacts act to determine a fractional included portion, and electrical circuits or branches of a circuit, one of which includes said fractional portion, another of which includes a measureable resistance-equalizer, by which linear measurements are indicated.

Electrical Location and Range Finding Instrument, J. Rapieff, 441,973. Filed March 10, 1890.

Claim 3 follows:

The combination of two telescopes or alidades movable at variable angles to a given base-line bearing a definite geographical relation, and a range and location indicator consisting of a plane table and map, independent indices intersecting to represent the vision-lines of the telescope and movable at variable angles to a given base-line bearing a corresponding definite relation to the map, and electrical transmitting apparatus, substantially as described, for synchronizing the movements of the indices with those of the respective telescopes.

Method of Finding the Range of Distant Objects, J. Rapieff, 441,974. Filed March 10, 1890.

Claim 1 follows:

The method of finding the range of a distant object, which consists in first determining a fractional portion of an electrical conducting body, which fractional portion bears in length a ratio to the variable base of a triangle included between two lines of sight converging at a constant angle upon a distant object, and second, measuring the electrical resistance of said length.

Indicator for Range-Finders, J. Rapieff, 441,975. Filed March 10, 1890.

Claim 1 follows:

The combination, in a range finding instrument, of two telescopes or alidades, both movable at variable distances apart, and an indicating device consisting of two movable adjacent parts connected, respectively, to said instruments, and an indicating scale or dial common to both said movable parts, upon which the variations of distance between the instruments are indicated irrespective of the position of such instruments with reference to a fixed point.

Lightning-Arrester, J. J. Wood, 441,999. Filed July 14, 1890.

A thermic device is arranged in sufficiently close proximity to the plates of a lightning arrester to cause it to be heated by an arc between the plates, and the consequent expansion of the thermic device is utilized to set in operation an arc rupturing device. The thermic device is located out of the path of the lightning discharge so as to preserve it from injury thereby.

Device for Utilizing the Water-Power of Falls, C. J. Zeitinger, 442,000. Filed April 19, 1890.

Device for utilizing waste water power for driving dynamos or other machinery.

Electric Switch, F. E. Fisher, 442,030. Filed July 7, 1890.

A hand switch with bell-crank lever.

Railways and Appliances:—

Electric Signaling System, J. W. Riggs, 441,703. Filed Sept. 12, 1889.

To prevent the derailment of trains when a drawbridge is open. Devices mounted on the drawbridge and in electrical connection with the track rails and insulating conductor, by which when the draw is open the circuit between a battery on an approaching locomotive and the track rails and the insulated conductor will be closed, operating an alarm or other signal in the locomotive cab.

Trolley-Stand, W. L. Emmett, 441,753. Filed Sept. 18, 1890.

For electric railways. To secure a variable and regulated pressure of the right degree upon the trolley pole in various positions. The trolley pole is attached, in opposite directions, to extensions on a pair of rocking levers, the rocking levers having a battery of springs connected between other extensions thereon.

Trolley-Covering for Electric Railways, H. Jones, 441,764. Filed Sept. 13, 1890.

The conducting rail is located above the ties and is protected by a shield covering its top and sides continuously, the side protection extending below the rail; the trolley-rod is bent into a U-shape bringing the trolley upon the top of the conducting rail under its protecting shield.

Gearing and Motor-Supporting Mechanism for Electric Locomotives, F. Mansfield, 441,771. Filed April 8, 1890.

The motor is supported entirely upon the car body and attached to it by jointed or swinging members. The gearing consists in the combination, with a car wheel axle, of a drive shaft pivotally swung to the axle so as to revolve about it, and a flexible connection between the armature shaft and the drive shaft, such as linked or other belting. Intended to relieve the speed-reducing gearing of the great stress incident to the sudden starting of the motor.

Automatic Electric Railway Signal, R. O. Owen, 441,773. Filed March 18, 1890.

Provides an automatic telegraphic railway signal by which the passage of a train past each station or section of track may be automatically signaled to the train dispatcher's office. A main line circuit is grounded at each station, or section of track, through contact springs or brushes carried upon the trains. The contacts at each station or section are spaced to represent the numbers assigned to such stations or sections.

Trolley-Wire Hanger or Support, E. H. Kitfield, 441,800. Filed March 12, 1890.

The hanger consists of two members, one of which attached to an insulator, is provided with arms to engage the trolley wire on its upper side, while the second member, provided with a longitudinal groove or channel to receive the wire, is secured and fitted into the first member. Designed to obviate the use of solder.

Electro-Magnetic Traction-Increasing System, M. W. Dewey, 441,828. Filed Aug. 25, 1890.

Electro-magnetic apparatus located along the line of railway where grades are heavy. Electro-magnets, with their cores in contact with the rails, distributed at intervals along a railway at points where it is desirable to increase the traction.

Moving Contact for Electric Railways, A. W. Adams, 442,003. Filed Dec. 28, 1889.

Contact or trolley consists of an endless belt or flexible band of conducting material passing over two pulleys supported upon the trolley pole, and moving by frictional contact with the conductor, being held against the conductor by a yielding pressure.

Secondary Batteries:—

Electrode for Secondary Batteries, J. Y. Bradbury and F. J. Stone, 441,818. Filed Nov. 16, 1889.

Electrode comprises a plate of supporting material having its opposite faces formed into alternate projections and depressions for the reception of active material. The opposite sides of the depressions are open, and laterally adjacent projections open into each other. The plate is preferably formed of strips of supporting material arranged side by side and each offset alternately in opposite directions, forming receptacles for the active material.

Secondary Battery, C. W. Kennedy and H. Groswith, 441,958. Filed Apr. 7, 1890.

Relates to secondary batteries of the class in which the active material is held in place by and between perforated plates of lead or other material, two of the plates, with the active material between them, constituting one electrode.

Claim 3 follows:

An electrode for use in a secondary or storage battery, composed of two perforated plates of lead or analogous material, having outwardly projecting knobs or studs integral with the plates, and inwardly-projecting annular raised burrs or bosses encircling the perforations and filled with active material confined between the perforated faces of the plates and raised flanges along the inner edges of the plates, substantially as shown and set forth.

Electrode for Secondary Batteries, C. W. Kennedy, 441,959. Filed June 28, 1890.

Claim follows:

An electrode for electric batteries, consisting of two or more plates of rigid metal coated on both sides with metallic lead, said plates being connected together with an intervening space filled with active material, and provided with apertures for the passage of the exciting liquid, substantially as described.

Telegraphs:—

Telegraph Circuit, F. W. Jones, 441,847. Filed June 24, 1890.

Designed for use in a main telegraph office where local circuits and branch office wires are supplied with current from dynamos, storage batteries or other similar sources, and to facilitate speedy connections between the sending and receiving apparatus in main and branch offices; also, to facilitate the easy and rapid connection of single Morse circuits with quadruplex or duplex circuits so that the messages may be automatically repeated between such circuits; also provides means for connecting the local circuits and apparatus of one duplex system with the local circuits and apparatus of another duplex system so as to permit an automatic transmission of messages from one system to another simultaneously.

NEW YORK CITY LIGHTING BIDS.

At a meeting of the Gas Commission, Dec. 4, Mayor Grant, Comptroller Myers, and Commissioner Gilroy being present, the bids for lighting the city with electricity for the year 1891 were opened. There were six bidders, as follows: The Brush Electric Illuminating Company 299 lamps at 43 cents and 45 cents; United States Illuminating Company 309 lamps at 43 cents; East River Electric Lighting Company 247 lamps at 44½ cents; Mount Morris Electric Lighting Company 171 lamps at 43 cents; Harlem Lighting Company 211 lamps at 43 cents and 50 cents; North New York Lighting Company 28 lamps at 50 cents.

Comptroller Myers offered the following resolution: Whereas, The prices named in the bids or estimates are excessive, Resolved, That the interests of the city demand that each and every bid be and is hereby rejected.

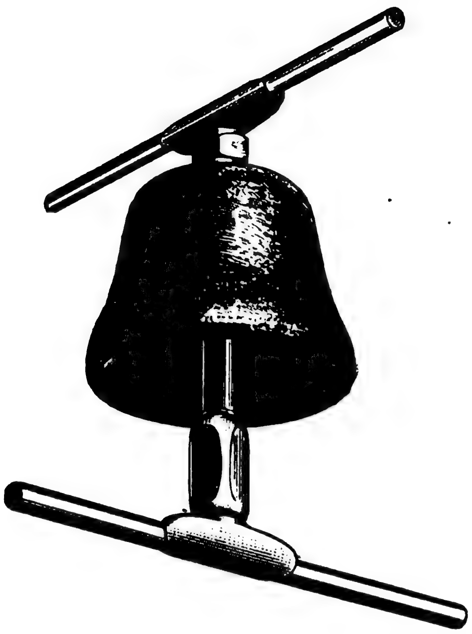
Commissioner Gilroy moved to table the resolution until the bids had been formally tabulated. Mayor Grant said that the motion was unnecessary. The bids would be tabulated before any action would be taken. The Commission then adjourned. All the bids received are from two to three cents higher than last year.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

ANOTHER FORM OF THE GOULD AND WATSON TROLLEY LINE WIRE INSULATOR.

WE illustrated in our issue of November 22nd a new form of clip, manufactured by the Gould & Watson Company, of Boston, for use on trolley line insulators. This week we illustrate another form of the same kind of clip as applied to a bell insulator. As will be seen, the clip is used both for the span wire and trolley wire. The bell, with the span wire clip, is first made fast to the



NEW GOULD AND WATSON TROLLEY LINE INSULATOR.

span wire by means of the bushing, and then the trolley wire is inserted into the bottom clip, and by means of the nut, which has a right and left hand thread, it is securely fastened in its place. The action is extremely simple and effective, and it can be applied to any line with the greatest ease.

THE CROSBY ELECTRIC CO.

The Crosby Electric Co., of 87 and 89 South Fifth avenue, this city, have purchased the business of the Federal Electric Co., heretofore carried on at 10 Cedar street, together with the stock and patents under which their goods are manufactured. They will fill all orders at once. The Crosby Co. have also received the highest award given by the American Institute Fair just closed, for all the batteries that they manufacture. It will be remembered that the Crosby Co. had a very fine and interesting exhibit at the Fair, illustrative of the great variety of uses and work to which their batteries could be applied.

ACTIVITY OF THE RAE ELECTRIC RAILWAY SYSTEM.

The Detroit Electrical Works are in a most active and bustling condition, owing to the large number of orders they are receiving for Rae electric railway equipments. During the past month they have been fortunate enough to secure a contract for fifteen 30 h. p. equipments mounted on Taylor trucks, for the Aurora, Ill., street railway lines, and they anticipate seeing the road started a day or two before Christmas. They have also contracted for the equipment of the Springfield Electric Railway & Improvement Co.'s road at Springfield, Mo., with ten complete equipments, mounted on Sheffield trucks. Last week Dr. Everett, president of the Lake View and East Cleveland, O., Road, ordered two complete equipments on Sheffield trucks for use on that road, the order being given after a thorough test of 60 days' practical running. This week they have received an order from the Joliet Ill., Street Railway Co. for a complete equipment, with Bemis truck, for use upon their existing electric road. It is stated further that the new company in Kansas City, Kan., has decided to put in the Rae system; while inquiries from all parts of the country are most numerous and pressing.

LARGE WESTINGHOUSE ORDERS.

The Westinghouse Electric and Mfg. Co. completed, during November, a month of business which has been one of the largest in the history of that corporation. The company shipped an aggregate of incandescent alternating current light machines of 80,000 sixteen candle power lamp capacity. Among the places where the Westinghouse system has been installed are Philadelphia, Pa., 750 incandescent and 300 arc lamps; South Omaha, Neb., 750 lights; Ballston, N. Y., 750 lights; Lima, O., 1,500; Aspen, Col., 750; Wellsburg, W. Va., 500 incandescent and 25 arc; Charleston, W. Va., 750, increase; Portland, Oregon, 100 arcs.

W. H. GORDON & CO.

The above firm, of 115 Broadway, have lately taken the general selling agency for the new and popular Star Electrix switches, sockets, cut-outs, etc. These specialties have but recently been put on the market, and have already made a name for themselves.

Mr. W. H. Gordon has just reported home from a week's trip in the West. While there he closed a contract with the Louisville Electric Light Co. for over 60 miles of Simplex T. Z. R. wire. Part of this, it is understood, is for the electric railway circuits and part for the circuits to carry the new Wood arc lights.

ROBINSON RADIAL CARS.

Of the Robinson radial cars ordered by the West End Railway Company, 14 of the car bodies are already completed and 35 more are well under way. The radial trucks for these car bodies are beginning to arrive at the central power station, and within a few weeks a large number of the radials will be running in the streets of Boston. The car bodies are 25 feet long, and will comfortably seat 17 to 18 passengers on a side. The height of the car bodies will be the same as in the radials now in use, that is, seven inches lower than the eight-wheel cars.

Col. George Truesdell, president of the Eckington & Soldiers' Home Railway, Washington, D. C., recently made some careful scientific tests with one of the Robinson radial cars having a 26-foot body, which he has on his road, and he states that in climbing grades the radial requires, on an average, two h. p. less than the ordinary four-wheeled cars. This is corroborative of the facts observed in connection with the running of the radials in Boston.

RAW HIDE PINIONS FOR ELECTRIC CARS.

In his recent annual report to the stockholders of the West End Street Railway Co., of Boston, President H. M. Whitney in alluding to the wonderful results obtained with the electric cars remarked that " the noise of the motors seems to be the greatest objection." There is vast improvement being made in this respect, however, and the Electric Merchandise Co., of Chicago, claim that the objection can be entirely removed by the use of their raw-hide pinions. They have already supplied about 75 electric roads with these pinions with uniformly excellent results. They are in receipt, for example, of the following letter from Mr. E. G. Connette, the superintendent of the United Electric Railway Co., of Nashville, Tenn.

" We have used your raw hide pinions and are very well satisfied with them; while the life of a raw hide pinion is not quite so long as a good bronze pinion the saving on the iron gear makes them quite economical. You will remember we purchased some of your pinions about five months ago, some of which are still in service. I have to-day sent you an order for 4 dozen."

THE CLARK ELECTRIC CO. AWARDED THE HIGHEST MEDAL.

The Clark Electric Company, Corbin Building, 192 Broadway, N. Y., received on November 29th, a special silver medal for their automatic safety device, awarded by the judges of the American Institute. The factory of the Clark Company was visited by them, and the safety device tested by cutting the electric wires and allowing them to fall on other wires; and in every instance the device proved its efficiency by removing all danger. The Clark Company have also received from the same source a Medal of Superiority for their arc lamp, run from incandescent current circuit, one of which was on exhibition at the American Institute Fair, and was much admired by visitors, being mounted in a very handsome and ornate fixture. The company are introducing this style of fixture for interior lighting for stores, theatres, public halls, etc. They have a lamp so mounted at present in their office, 192 Broadway, running from incandescent current. Mr. Clark, the electrician of the company, is an indefatigable worker, and is a fertile genius in inventing new and useful electrical apparatus.

THE BARRIETT ELECTRIC CO.

This company has just been organized to build the dynamos and motors of Mr. S. L. Barriett, well known in the electric motor field. They will start by placing on the market the smaller sizes designed for fan work, which will be followed by the larger. The officers of the company are E. L. Moody, president; J. U. Hoey, secretary and treasurer; and S. L. Barriett, general manager and electrician. The offices of the company are in the Equitable Building, N. Y., room 32.

NEW OFFICES OF THE INTERNATIONAL OKONITE COMPANY (LIMITED).

The almost general adoption of electricity for commercial and household uses, has made the demand for telegraph, telephone and electric light insulated wires and cables a large and steadily growing one. This has naturally given a decided impetus to the business growth of concerns engaged in the manufacture of such goods. In no case is this more noticeable than in the rapid progress of the International Okonite Company (Limited), of New York and London.

The new factory of the International Okonite Company (Limited), at Passaic, N. J., being practically finished and in tip-top running order, this enterprising and progressive concern have turned their attention to improving their New York headquarters, 13 Park Row, both in facilities, appurtenances and appearance. By the acquisition of three or four more rooms in addition to those formerly occupied by them, they have secured every facility for the systematic and expeditious carrying on of their immense business and have located themselves in quarters which should please the most fastidiously inclined.

The new offices of the company, richly artistic in all their fixtures, have an air of refinement and propriety in their elegance, which prevents any idea entering the visitor's mind of display in decoration solely for the sake of show. Everything is elegantly serviceable. As you step from the elevator at the fourth floor of the building, 13 Park Row, you are landed immediately in front of the entrance to the company's quarters. A door opened, ushers you into a reception or waiting room. Here one makes known his business with the company before he can proceed further. This reception room is artistically and comfortably furnished. In the centre is an immense table of finely carved and polished oak, on which are scattered in pleasing confusion, the latest issues of all the electrical journals. They are at your service if you care to peruse them. Comfortable, leather cushioned oak chairs and an oaken settee—a very artistic piece of work—complete the furnishing, and make the time you may be detained here pass pleasantly. The offices of the Okonite Company comprise six sections or departments, formed by partitions and artistic oak railings. These partitions are in themselves the main decorative features of the suite of offices, being of highly polished carved oak, the upper portion of dull glass, and surmounted with a decorative miniature railing or cornice. All the woodwork is of oak, also the furniture. Having passed muster at the hands of the office manager, Mr. Hodgkins, who, through a window placed in a partition at the rear end of the reception room, is the inquisitor, the caller proceeds to the inner or office proper.

The private offices of Capt. Willard L. Candee, Mr. Geo. T. Manson, Mr. H. Durant Cheever and the sales agent's quarters are at the further end of the reception room and on its left, as you enter. The general sales agent, Mr. T. McCoubray, and assistants, occupy an oblong room which forms a sort of hall between the private and general offices. They are replete with every facility for the convenience of those here located; desks, chairs and incandescent light; in fact the offices of the company are lighted throughout by electricity. At one end of this hall or room, is stationed the safes, telephone cabinet (a very ornamental and useful piece of furniture) and steam radiator, over which hangs the office clock. At the farther end, screened by a nicely arranged portiere and railing, is the wardrobe and lavatory.

To the left of this department and facing the busy thoroughfare, Park Row, are the private offices of Capt. Candee, Mr. Manson and Mr. Cheever. They comprise most of the space occupied by the old quarters of the company. These rooms are well lighted, equipped with desk, chairs and cabinets, of finely carved and highly polished oak. Appropriate pictures in oak frames decorate the walls, and a quiet elegance pervades the whole. Taken separately or collectively they are in every way fitted for the convenience and comfort of the well-known personages who will hold undisputed reign in their precincts. Communication from each of these offices is made to the departments presided over by Messrs. Hodgkins, Brumley and Ashton, by means of push buttons and speaking tubes, all of which allows the great business carried on by this concern to be done expeditiously and without noise or confusion. The financial or business part of the Okonite Company offices is located at the further end of the reception room, and on its right as one enters, a finely wrought oaken railing separating this department, of which Mr. Hodgkins is the head and leading spirit, form the rest of the office. Once past this gentleman's desk, which is situated at the entrance, you notice the admirable and comfortable arrangements made for the working force of clerks, bookkeepers, stenographers, etc. There is a place for every one and everything. Communication between the several departments here represented and Mr. Hodgkins are made very complete by the aid of push-buttons and speaking tubes.

The International Okonite Company in their present quarters may safely lay claim to an office which, in point of convenience and elegance, cannot be surpassed by any of its size in the city, and such an office as a firm of their commercial importance fully deserve.

THE HEISLER ELECTRIC LIGHT CO.

The proprietors of the Heisler system of long distance series incandescent electric lighting have found it necessary to transfer the manufacturing of their apparatus from St. Louis to their new and commodious works located at Gloucester, New Jersey, where with enlarged space at their command, and increased facilities, they will be enabled in the future to meet the constantly increasing demand for their apparatus. In announcing this, they say:—

"The extensive introduction and adoption of this system within the past two years for commercial, street and alley lighting, has made it necessary to increase the manufacturing facilities. It is now a recognized fact among those most interested in incandescent installations, where it is necessary to distribute lights over large areas, that the Heisler system is the only one that fully fills the requirements. The Heisler system's merits are fully recognized and acknowledged to thoroughly overcome these very serious conditions by making it possible to distribute any number of lights, from 160 thirty-two candle power lamps to the full capacity of our largest dynamos, over an area of territory that could only be covered by 50 miles of No. 8 B. & S. gauge wire, and suffer no drop in the candle power of the lights, the lamps farthest away burning as brightly as those nearest the dynamo, and the loss due to the resistance of the line (8 B. & S.) being equal only to one 32 c. p. lamp per mile. The efficiency of our dynamo under these conditions makes it possible to obtain 6¼ thirty-two candle power lights per mechanical horse-power expended, less the friction load of the dynamo, producing a white and brilliant steady light, superior to the incandescent lights usually produced by other systems. The improved automatic regulator used in connection with this system controls and maintains a steady and uniform light, and at the same time dispenses with all translating devices in the station and upon the circuit. The only device (other than the dynamo) used in the installation of the Heisler light is the improved combined automatic cut-out and lamp socket, a perfect device in itself, being adapted to hold any size lamp from 10 up to 150 c. p., containing no parts liable to get out of adjustment, and the cut-out feature is always accessible for removal without the liability of interrupting the circuit while manipulating the same. The housing of the socket is composed of insulating material and the cut-out can be renewed at a cost of less than one cent. We continue a St. Louis agency where there will be kept on hand a supply of lamps and materials for repairs, as well as immergency experts, whose duty it will be to look after the various installations west of the Mississippi river."

All orders and communications should be addressed to the Heisler Electric Light Company, Drexel Building, Philadelphia, Walter S. Smith, general manager.

THE RILEY ELEVATED SYSTEM.

It is stated that negotiations have been concluded as the result of which there will be an elevated road built between the two exposition depots of the World's Fair, at Jackson Park and Lake Front, Chicago. The Riley Co., of Boston, is to build and equip the road, which is estimated to cost about $450,000 per mile.

THE ELECTRICAL SUPPLY CO., CHICAGO.

The following circular has been issued by the Electrical Supply Co., of Chicago:—"Owing to the fact that much of our catalogue matter has at various times been copied into publications by other electrical companies, we deem it necessary to call attention to the fact that our catalogues are thoroughly covered by *copyright*, which fully protects all the descriptive matter, and cuts of articles, as well as the general arrangement of both. This being the case, anyone who reproduces our catalogues by photographic process or otherwise, so that the duplicates appear as in our original books, infringes our copyright and lays himself liable to legal action in consequence. We have justly won an enviable reputation as the producers of carefully compiled electrical trade catalogues, and in justice to ourselves, we cannot consent to an infringement of our legal business rights without a protest."

ELECTRIC GAS LIGHTING CO., BOSTON.

The above company have just issued a circular as to the Bubier battery compound, which they handle, made by the Bubier Mfg. Co., of Lynn, Mass. It is sent out in neat boxes, in sizes to make 1 pint, 2 quarts, or 4 quarts of solution. It is intended especially for Grenet, medical and bichromate plunge batteries.

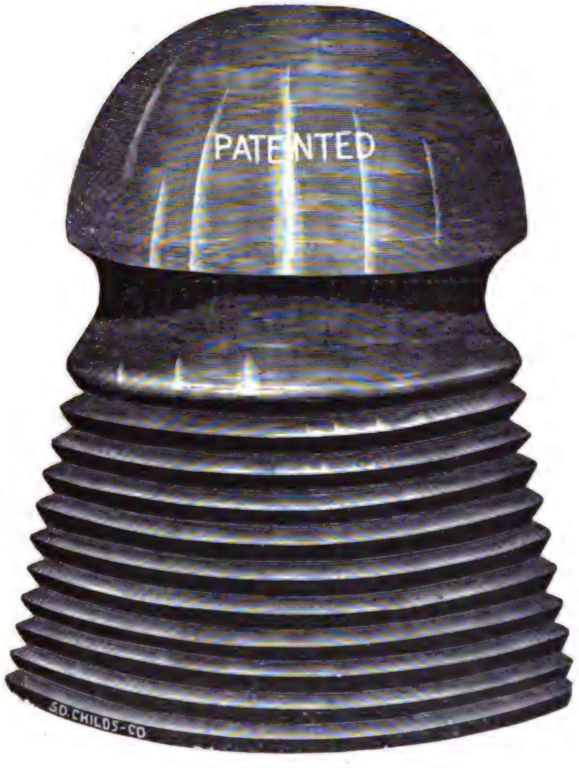
THE BAIN INSULATOR.

We present this week a cut of a new high resistance glass insulator, the invention of Mr. Foree Bain, of Chicago.

The insulator is made extra strong and is especially adapted to heavy work, such as carrying large primary wires, and particularly feeder wires for electric railroad work. The corrugations which are made both outside and inside of the apron increase the distance from the wire to the pin fully 100 per cent., and it is claimed that water will, in passing over the edges of the rings, become thin and broken, and on reaching the inside of the glass will drop off rather than creep over the inner obstructions to the pin.

Another point in favor of this form of insulator is that the many surfaces will reflect the light under the glass in such a way as to keep insects out, obviating a source of much annoyance where plain dark glass is employed.

This insulator will cost a little more to manufacture than the



The Bain Insulator.

ordinary plain glass insulator, but the inventor claims that an advance of a few cents per mile in the cost of construction will not be any objection where a high class of work is desired.

Mr. Bain has assigned his patent to the Central Electric Company, of Chicago, who are now sole owners and by whom the article is being placed upon the market.

THOMPSON, REED & CO.

Thompson, Reed & Co., 31 Liberty St., this city, is the name of a new engineering concern. The gentlemen composing it have been connected with the development of the electrical business for some time, and have the benefit of experience. They will contract to build street railways of any system, and to act as consulting engineers.

CONSOLIDATED ELECTRIC STORAGE CO.

Arrangements have been made with the North American Phonograph Co., whereby they are to use exclusively the storage battery made by this company, of 120 Broadway. This means a good deal, when it is taken into account that the North American Co. have 35 sub companies in different parts of this country, and that new ones are being formed every day.

ELECTRIC LIGHT CONE REFLECTORS.

We illustrate on this page some of the devices recently brought out by the American Reflector Co., of Fifth and Cherry streets, Philadelphia, in the line of reflectors for electric light purposes. The diffusion of light scientifically is not an easy problem, and the value of a good reflector in creating soft and steady, yet strong, effects is not as fully realized as it might be. One design is

Fig. 1.—Reflector for Clusters.

a silvered glass reflector to fasten on a ceiling, to be used with a single incandescent light. Fig. 1 shows a silvered glass reflector for clustered incandescents, it being intended to serve specially for lighting show windows, stores, offices, etc. Fig. 2 shows one of their suspended silvered glass cone reflectors, as arranged for incandescent lamps. This is made with the double cone, as shown,

Fig. 2.—Silvered Glass Cone Reflector.

and the light is therefore greatly enhanced in brilliancy and effectiveness. The company have also adapted their corrugated silvered glass head light, so that it can be utilized for electric cars, with incandescents run from the trolley circuit.

ELECTRIC CARS IN SAVANNAH, GA.

The electric cars in Savannah, Ga., began running on Nov. 3, and the conductors had a delightful time of it. Every one of the four cars was jammed, and 5,000 nickels were turned in to the company that night.

THE DEMAND FOR EUREKA TEMPERED COPPER.

The Eureka Tempered Copper Co., of North East, Pa., report large shipments of commutator segments in November to the Edison General Electric Co., the Westinghouse Electric Co., the Brush Electric Co., the Wenstrom Consolidated Dynamo and Motor Co., the Electro-Dynamic Co., and nearly all the manufacturers of motors in the United States.

At a meeting of the North West R. R. Club, held at Union Depot, St. Paul, Nov. 7th, Mr. C. F. Ward, M. M., of St. Paul and Duluth road, in the discussion of the best methods of locomotive side rods, said that he wished that some member would try tempered copper as a material for brass with solid rods. He had used the copper on some cross heads, the engine was turned out last June, and had been running ever since without any perceptible wear on the gibs.

The Eureka Co. were awarded the John Scott medal by the Franklin Institute, of Philadelphia, at the November meeting. The company report large orders received from their goods for electrical purposes and for bearings, and have been compelled recently to double the capacity of their plant.

CARD ELECTRIC DYNAMO AND MOTOR CO.

In order to acquire the increased facilities rendered necessary by their increasing business, this company is moving its works into a new building, corner Second and Plum streets, Cincinnati.

Among recent installations of the Card Co. may be mentioned a 150-light plant in the Argonaut cotton mill, Covington, Ky.; a 75-light plant in the works of MacNeil, Urban & Co., the safe dealers, of Hamilton, O., and also a 75-light plant in the factory of the Cincinnati Spring Co., of Cincinnati.

ELECTRIC CARS POPULAR IN INDIANAPOLIS.

Among the signs of the popularity of the electric cars in Indianapolis it is mentioned that they have affected hack hiring.

"Business is dull since the electric line was completed," said a livery-stable man.

"What's the relation between the two?"

"Why, people take their rides on the electric car—go to the parks and have all the outing they care for at ten cents (round trip). That beats two or three dollars. But the board bills at livery stables are about as large as heretofore."

WESTERN SALES OF THOMSON-HOUSTON APPARATUS.

The Western Isolated Lighting Department of the Thomson-Houston Co. has sold plants as follows: Democrat Printing Co., Madison, Wis., 100-light incandescent; L. E. White, Greenwood, Cal., 30 arc light; St. Louis, Mo., R. R. Co., for power house and car barns, 400 incandescent; G. F. Culmer & Bros., Salt Lake City, Utah, 100 incandescent, to be used in connection with a plant for lighting an office building as sold some months ago.

THE SHAVER FACTORY VISITED BY FIRE.

On December 2 a fire occurred in the factory of the Shaver Corporation, at 78 and 80 Cortlandt street. The damage done was of limited amount, reaching about $3,000, mostly on telephones and Gillette magneto bells, together with about 2,000 of the ingenious Shaver spiral screw drivers. The company has leased another factory at 50 Cortlandt street, and will be ready to resume delivery of goods some time this week or early next.

THE STANLEY ELECTRIC COMPANY.

The new Stanley electric company was organized at a meeting held Saturday evening, says the Pittsfield, Mass , *Eagle*, of Dec. 4, when these officers were elected: President and treasurer, Charles Atwater; clerk, George H. Tucker; directors, William Stanley, Jr., W. A. Whittlesey, Charles Atwater, George H. Tucker, Henry C. Clark, Charles E. Hibbard and W. W. Gamwell. Another meeting was held last evening when the affairs of the company were discussed, and plans for getting under way were considered. It has not been definitely settled where the new company will locate, but the probabilities are that a portion of the new Morton block on McKay street will be leased. This building is very substantially built and is in every way suitable for the purposes desired. The new company will probably get started in about six weeks and will first begin the manufacture of converters. Several skilled machinists and a number of helpers will be employed at first, and the number will be increased as the extension of the business warrants. Much heavy machinery will be used. Later on the company will engage in the manufacture of different kinds of electrical apparatus, and bids fair to become in time, a very considerable institution. The company was projected by Mr. Whittlesey who, by the way, is a wide awake and energetic as well as most courteous business man. The choice of officers has been most fortunate as they are all practical and capable business men. The new company is also to be congratulated on having Mr. Stanley so directly interested in it, as his knowledge of the electric business coupled with his remarkable inventive genius, makes him a most valuable man for such a concern. The new electric company starts off under the most favorable auspices and its future is certainly very bright. It is a grand accession to the business interests of Pittsfield, and the new city is to be congratulated on being selected as the home of such a promising concern.

NEW ENGLAND TRADE NOTES.

THE GOULD AND WATSON COMPANY, BOSTON.—On page 561, of our issue of November 19th we illustrated the new Cushing switchboard for electric lighting in theatres, and we desire to call more particular notice to the moulded mica insulating material of which the insulating parts of this board were made. Messrs. J. P. Cushing & Co., who manufactured the board, gave a great deal of attention and preliminary experiments to the selection of this material, and it was found that moulded mica was the most suitable of any material experimented with, it being extremely hard and strong, perfectly waterproof and fireproof. Undoubtedly this material is coming rapidly to the front as a reliable and durable insulator, and its merits ought to be thoroughly investigated by all manufacturers of electrical apparatus.

THE GETHINS ELECTRICAL MANUFACTURING CO., of Boston, have added a new department to their enterprise. Special provision has been made for the charging of storage batteries at their offices at 620 Atlantic avenue, for which their cell is particularly adapted. Anyone using storage batteries can now readily and promptly have their batteries charged by making arrangements with the Gethins Company, a privilege which will be readily appreciated by many.

WESTERN TRADE NOTES.

MR. SPRUANCE, of the Star Electrix Company, of Philadelphia, was a welcome visitor to Chicago last week.

MR. GEORGE CUTTER, whose name is so well and widely known in connection with various and important lines of electric development, is again in business for himself as a dealer in electric specialties. From his handsome new quarters in The Rookery he intends to push the most improved appliances for electric light and power plants. He controls a number of such devices, which are very highly thought of, and many of which are the product of his own fertile inventive talent, and, besides, he is arranging to handle numerous others of equal merit. In addition to this portion of the industry, his long and varied experience in all kinds of electrical work would seem to fit him peculiarly for acting as consulting electrician, to which work he will devote a portion of his time. As has always been his custom, he will be surrounded by a picked corps of assistants, and this, together with the success with which he has previously met, bespeaks for him a most prosperous career. Mr. Cutter in his new field will undoubtedly receive the efficient support of his many friends, who hold him in the highest esteem.

THE ELECTRICIANS' TIME CO., 167 Dearborn street, Chicago, who deal so largely in watches, diamonds, jewelry, etc., will issue a new and complete catalogue, profusely illustrated, January 1st, 1891. They make a specialty of catering to the electrical trade, and are doing a large and thriving business. The Giles non-magnetic shield which they furnish is a complete preventive of magnetism affecting watches, and is in large demand. Early application should be made for a copy of the new catalogue, as many new and interesting specialties will be found therein.

MR. C. B. HANNA, the popular general agent of the Carpenter-Nevens Electro Heating Company, is at the Wellington Hotel, Chicago. He is making arrangements for a large and most complete factory here for the manufacture of their electric heating apparatus. Their system of electric car heating, fully illustrated and described in the last issue of THE ELECTRICAL ENGINEER, is meeting with widespread approval, and every street railway man should investigate its numerous and marked advantages and merits.

THE GREAT WESTERN ELECTRIC SUPPLY CO., 190–192 5th Av., Chicago, are now busily engaged in preparing a new and complete catalogue of their various electric light, power and street railway supplies and specialties, which they expect to issue about the first of the year. This action has been rendered an imperative necessity, owing to the enormous demand for their sketch catalogue, which they recently brought out. The catalogue of supplies and house goods will occupy a whole book, and the fixture catalogue another; and both will compare very favorably with anything of the kind ever brought out.

THE
Electrical Engineer.

VOL. X. DECEMBER 17, 1890. No. 137.

THE RIKER LOW SPEED MULTIPOLAR MOTORS AND DYNAMOS FOR CONTINUOUS CURRENTS.

BY A. L. RIKER.

THE subject upon which I desire to advance a few ideas, has received considerable attention lately from electrical engineers. The point which I desire to emphasize is the advantages to be gained by low speed motors over high speed motors or dynamos.

In a dynamo plant any saving of space is a very important item. Most high speed dynamos are belted to the engine, all of which occupies space. With the low speed dynamo the shaft of the generator and the shaft of the engine (which latter can in this case also be of low speed) are coupled directly together; thus not only saving by direct connection, but power and wear and tear on plant by effecting a decrease in friction. The reduction in friction is about nine times, meaning a proportionate reduction in wear and vibration. There is no counter shaft required, nor is there loss by slippage of belt or driving cones.

The low speed motor has similar advantages and its consequent noiseless running makes its employment possible, where the use of a high speed motor could not be considered. To all users of machinery the economic advantages of low speed machines will be at once apparent.

As multipolar machines and their operations are very well known, I will not go into the subject generally, but will confine my remarks to a multipolar machine of my own

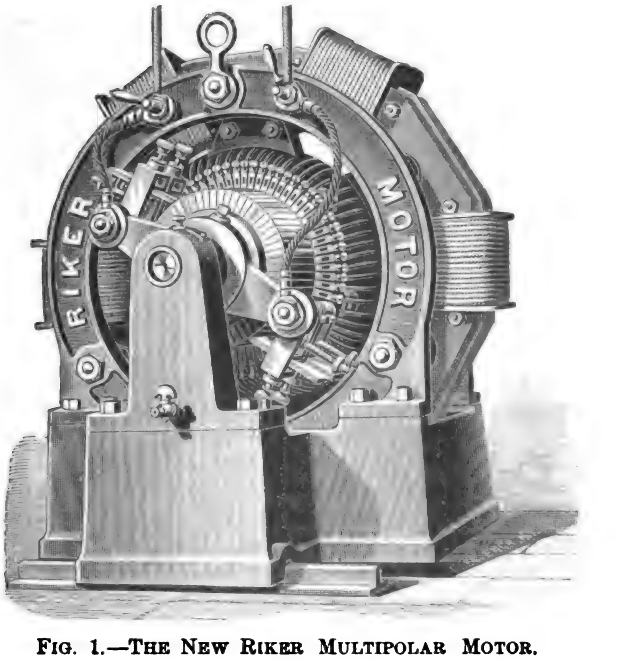


FIG. 1.—THE NEW RIKER MULTIPOLAR MOTOR.

design, which embodies several novel and important improvements.

In a multipolar machine it is necessary to have as uniform a field as possible, and as the consequent pole type of magnet on closed magnetic circuit is most uniform, I have adopted it. The accompanying engraving, Fig. 1, is a view of my 5-h. p. motor; Fig. 2 is a diagram of the magnetic circuit of the machine under consideration. As will be seen by reference to the diagram, the magnetic circuit is very short, completely surrounding the armature and concentrating the lines of force, so that very little copper is used and a high efficiency is attained.

The path of the lines of force forms almost a circle. The

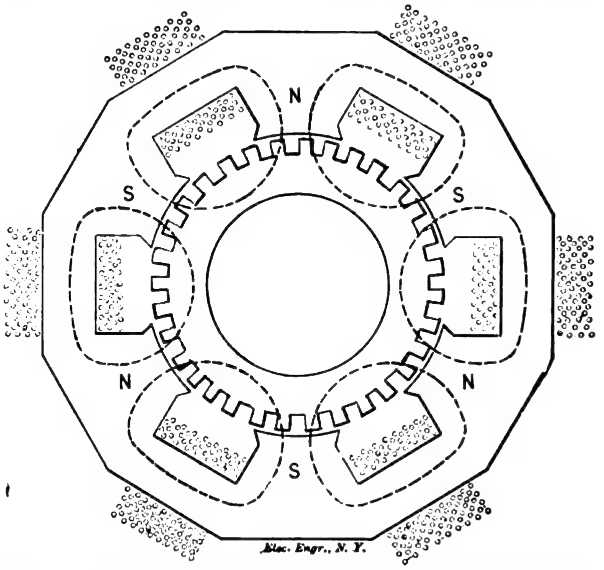

FIG. 2.—MAGNETIC CIRCUIT, RIKER MULTIPOLAR MOTOR.

field is produced by six magnetizing coils producing six consequent poles. The entire field is composed of plates of soft sheet iron, built upon six bolts of non-magnetic material, which pass through the pole pieces, three of which are continued through and bolted to the supporting rings on either side of the machine.

As in all machines of my design, the armature is a toothed ring, supported by six bolts passing through and insulated from the armature core and mounted on two spiders of non-magnetic material, and which, in turn, are keyed to the shaft. The winding is the ordinary Gramme winding.

In a six-pole machine it is necessary to use either six brushes or to cross connect the commutator. The first method is preferable where carbon brushes are used, but where copper brushes are employed cross connecting is better. As the placing of six brushes around the commutator is well understood, I will describe my method of cross-connecting by which two brushes placed diametrically opposite are used as in a two-pole machine. These cross-connectors are placed inside the commutator, and their construction will be understood by referring to Fig. 3, which is an end view of one of them.

A sectional and longitudinal view of the commutator are given in Figs. 4 and 5. Here A represents the commutator sleeve, which is insulated from the cross-connector C by the air space B. Each cross-connecting ring is stamped out of sheet copper and is let into and soldered to three bars placed respectively 120, 240, 360 degrees apart in the commutator, as shown in Fig. 5.

These rings are thoroughly insulated from each other and are entirely enclosed within the commutator, prevent-

ing any danger of short-circuiting and making the commutator as compact as that of a two-pole machine.

Another feature of this machine, which is among the first in importance and one that is often overlooked, is the method of lubricating. A very simple and efficient oiler

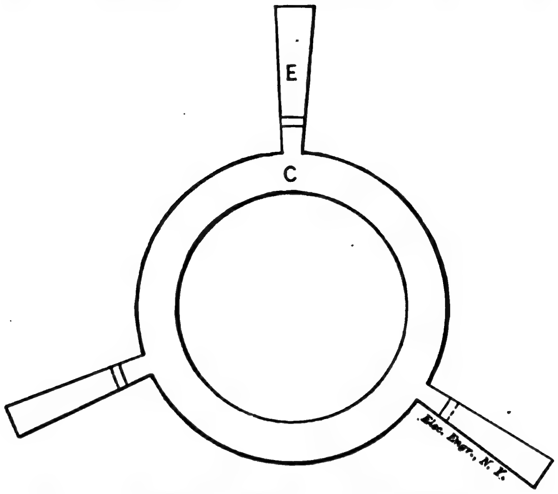

FIG. 3.—CROSS CONNECTOR FOR COMMUTATOR.

has been applied to them. The bearings are cast hollow and the bushings, through which the armature shaft runs, are slotted, exposing the shaft, over which, and dipping into the oil well below, runs a chain acting on the principle of the chain pump; this thoroughly oils the shaft and is entirely automatic in its action.

The bearings are so constructed that they cannot (as it is familiarly expressed) "sling oil." They require no attention further than to be filled once a month and the waste oil drawn off.

These machines are built from 5 h. p. upward. A special adaptation of this multipolar type is constructed for railway work to run at 400 revolutions per minute and is geared direct. This machine weighs about 60 pounds to the horse-power.

Aside from the question of speed, a number of minor

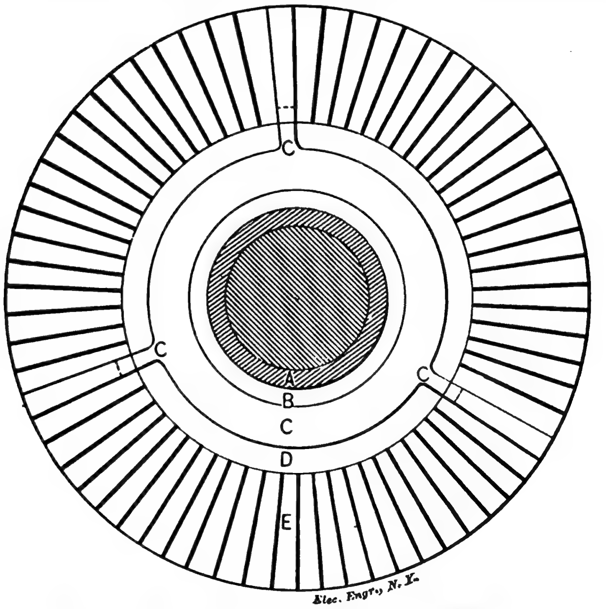

FIG. 4.—COMMUTATOR AND CROSS CONNECTOR.

points, which go far toward making a perfect machine, have received considerable study. Among others, attention is called to the brush holder and also to the binding posts to receive the wires from the mains.

The following are the data relating to the construction of my 5, 10 and 20 horse-power machines: 5 h. p. motor; Speed, 550 revolutions per minute; weight, 450 pounds; armature resistance, .166 ohm; shunt field, 100 ohms.

10 h. p. motor: Speed 550 revolutions per minute; weight 800 pounds; armature resistance .08 ohm; shunt resistance 75 ohms.

20 h. p. motor: Speed 550 revolutions per minute;

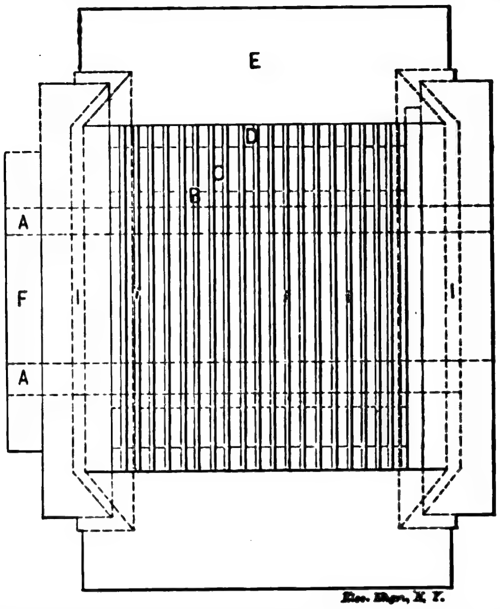

FIG. 5.—COMMUTATOR OF RIKER MOTOR, SECTION.

weight 1,150 pounds; armature resistance .037 ohm; shunt resistance 27 ohms.

ELECTRIC MOTORS TO TUNNEL IN THE ARGENTINE REPUBLIC.

The new railway which is to connect the Argentine Republic with Chili will necessitate the boring of eight tunnels through the Andes mountains of a total length of 15,875 m., or nearly 10 miles. These tunnels, in whose construction water power and electricity are to be largely employed in a novel form, have already, says *Engineering*, been commenced at 20 points. Since August last a cataract of the Juncalillo river, which has a fall of nearly 600 ft., has been made use of to supply the power in carrying out the boring operations in the tunnels of Portillo, La Calavera and La Cumbre. The Portillo tunnel takes a serpentine course through the massive rock, and its upper end emerges at the mountain side, 450 ft. above the entrance. The water of the Juncalillo cataract is conveyed through steel pipes half a meter in diameter for the distance of about a mile to the Juncal station. The boring machines employed in these three tunnels require a force of 1,000 horse-power to drive, and this is obtained by converting the water power into electricity. The water which is carried through the steel pipes is made to set in motion 10 turbines, each of 80 horse-power, which are connected with the electrical machines. The electricity thus produced is conducted through strong, insulated copper cables to Juncalillo and Calavera. From Juncalillo air-pressure machines are also supplied in the serpentine tunnel leading up to Portillo. From Calavera four 80 horse-power dynamo machines generate the electricity for the Cumbre tunnel, where six borers, all working at the same time, are driven by eight air-pressure engines. On the Argentine side of the mountains another cataract, near Navarro, has been similarly used for driving four turbines, each of 80 horse-power. Owing to the distance of the western smaller portion of the Cumbre tunnel, water power cannot there be employed, and the borings are being carried out by hand. Wherever water and electricity can be used, the boring operations are performed, it is estimated, fully four times as rapidly as they would be by hand. The cost and progress of the borings accomplished by this novel application of water power and electricity cannot at present be estimated, but the figures, which will be made known on the completion of the undertaking, can scarcely fail to prove of considerable interest to the engineering profession.

A CHARGE INDICATOR FOR ACCUMULATORS.

At a recent meeting of the Société Internationale des Electriciens, M. Gaston Roux described a form of direct reading charge indicator devised by him for use with accumulators. The apparatus is based on the fact that within certain limits the density of the electrolyte varies according to the quantity of electricity stored in a storage cell in a chemical form. Experiments carried out by M. Roux show that the temperature correction is entirely negligible between 0°C and 30°C. M. Roux employs a long cylinder reaching nearly to the bottom of the cell in order to take into account the want of homogeneity of the liquid. This cylinder is hung from the end of the short arm of a small lever, which should be horizontal when the cell is fully charged. On the same axis as the lever, and on the same side as the cylinder, there is arranged, at an angle of 45 degrees with the lever a small rod, along which a small weight can be screwed. On the long arm of the lever there is also an adjustable weight. At right angles to the lever there is a long pointer moving over an equally-divided scale. When the cell is discharged to its working zero, the pointer is brought to the scale zero by adjusting the weight on the long arm of the lever. When the cell is fully charged the pointer is brought to 100 by adjusting the weight on the rod fixed at 45 degrees with the lever. The instrument being thus adjusted for a particular cell the percentage state of charge of that cell at any moment is seen from the position on the scale occupied by the pointer. An instrument such as this should prove of considerable use in an isolated installation, where a storage battery is left in the hands of an unskilled attendant.

THE ELECTRIC METER COMPETITION IN PARIS.

The Municipal Council at Paris in conformity with the recommendations presented by M. Sauton has named the following gentlemen as part of the jury to examine and report upon the electric meters submitted for competitive test: MM. Mascart, Potier, Hospitalier, Cochin, and Lyon-Alemand. The members to be nominated by the administration of works have not yet been designated. Among the American meters submitted for test are the Thomson, the Walker and the Grove.

THE CLAUS-EASTON INCANDESCENT DYNAMO.

There was a time when dynamo construction was very largely a matter involving experiment in order to determine the best proportions and methods of construction, but the progress which has been made is such that the results to be obtained from any one design may be predicated with an accuracy which is second to that afforded by no other prime mover or generator of energy. It is also worthy of note that besides the increased accuracy and simplicity of electrical construction, the mechanical design of machines has been not less the subject of study and improvement. A machine in which both these essential elements have been well brought out is that illustrated in the accompanying engravings and which is known as the Claus-Easton dynamo. It is now being constructed by the Easton Electric Co., of this city, whose arc lighting apparatus is already well known.

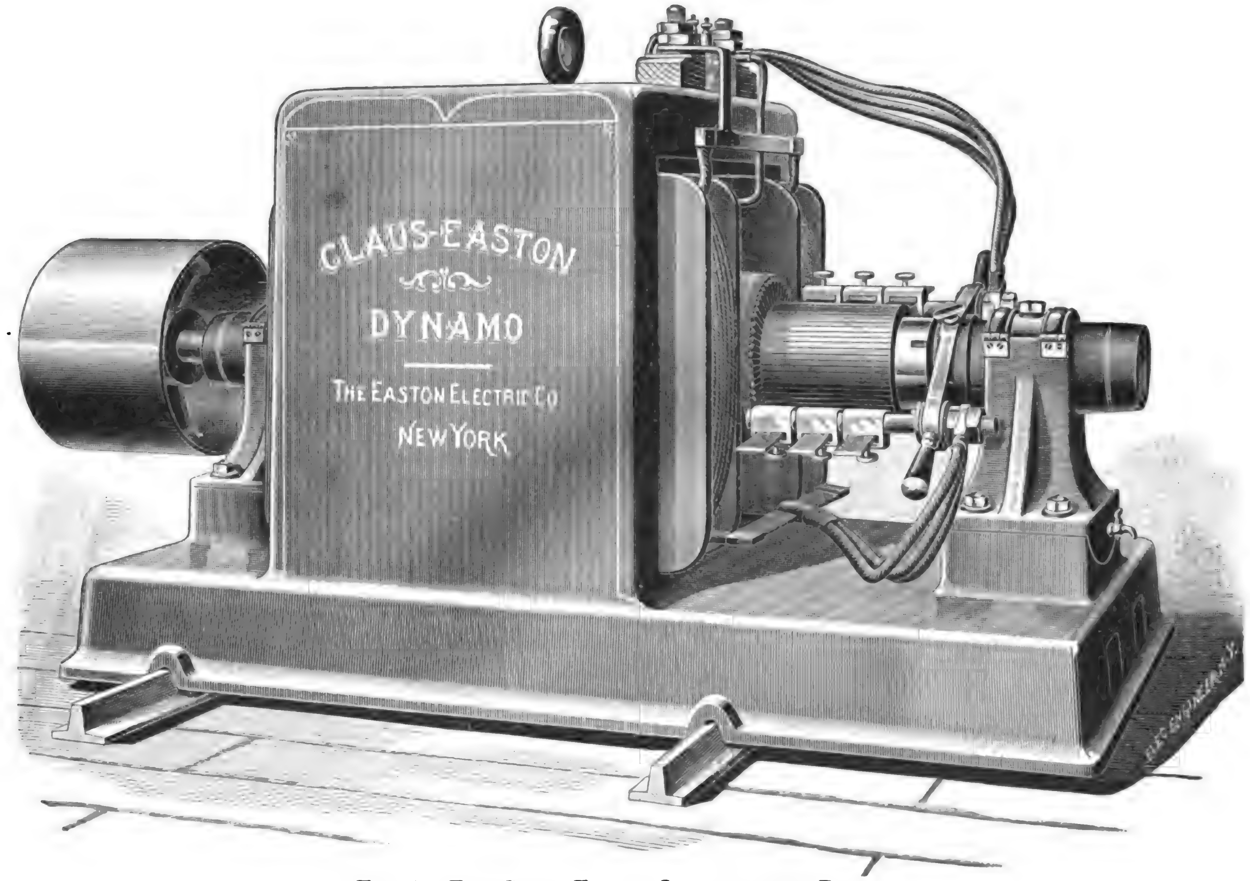

Fig. 1.—The Claus-Easton Incandescent Dynamo.

The simplicity of construction of the Claus-Easton machine will be well understood from the illustrations, Figs. 2 and 3, which show the same in section and in elevation. The entire magnetic frame of the machine, including the base, consists of but a single casting, which requires merely the boring out of the armature space between the pole pieces and the bearings for the shaft to complete it for the reception of the armature. The magnet coils are wound on bobbins in a lathe and slipped over the magnet cores. The mechanical construction is, therefore, of the most simple character imaginable, so that any repairs which may become necessary can be effected in the most simple manner in the least time.

The electrical details of the machine have also been worked out very carefully. The machine illustrated in Fig. 1 is intended for 800 half-ampere 16 c. p. lamps, and is, therefore, designed to give a current of 400 amperes. The armature is of the Siemens type, built up of laminated

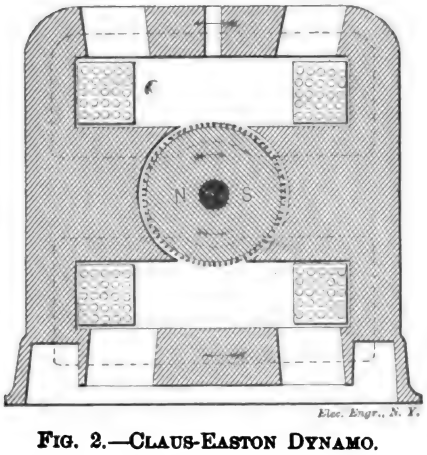

FIG. 2.—CLAUS-EASTON DYNAMO.

sheet iron and has a resistance of 0.0096 ohm. The machine in order to maintain constant difference of potential at all loads is compound wound, the shunt having a resistance of 9.177 ohms, and the series coil a resistance of .0164 ohm. With the winding adopted, the regulation is so close that no perceptible variation of po-

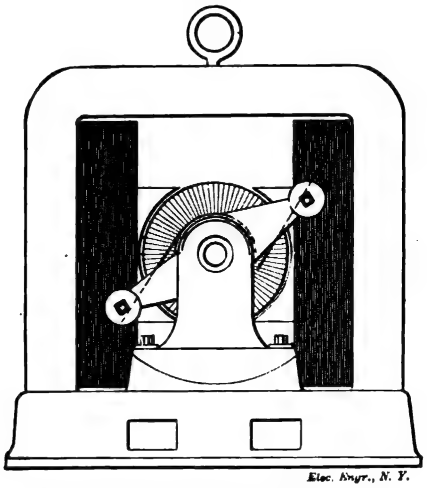

FIG. 3.—CLAUS-EASTON DYNAMO.

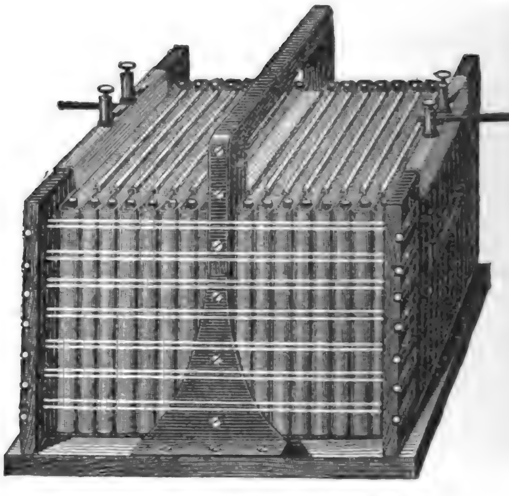
tential occurs between full load and practically no load. These machines are now being built in various sizes and those in use have given general satisfaction.

REYNIER'S HIGH VOLTAGE ELASTIC ACCUMULATORS.[1]

FOR some time past M. Emile Reynier has been at work perfecting a battery designed to afford in a single compact structure a high voltage and at the same time have the necessary qualities of solidity and portability. As a result, the battery has taken the shape illustrated in the accompanying engraving. It consists of 16 plates mounted in flexible pockets, so as to have a certain amount of elasticity. These elements are placed flat, one against the other, and compressed between two end plates of wood by means of rubber spring bands. A bridge, consisting of hard wood impregnated with a waterproofing material, carries the whole, which may be suspended or rest upon its base, as desired.

The spring arrangement gives to the active solid matter an artificial elasticity, which results in large specific power and storing capacity. The continuous compression of the plates, insulators and flexible pockets insures for these thorough protection against shaking and rough handling. Each of the pockets into which the plates are inserted is closed on top by means of a flexible and insulating stopper.

We give below the principal figures relative to the cell,



REYNIER'S ELASTIC HIGH POTENTIAL ACCUMULATOR.

which has 16 couples and which is known as the horse-power-hour type.

E. M. F.	32 volts.
Available fall of potential	28 volts.
Current discharge	3 to 6 amperes.
Normal power, about	150 watts.
Capacity	30 ampere hours.
Available useful energy	740 watt hours.
External dimensions: Length	0.40 metre.
External dimensions: Breadth	0.30 "
External dimensions: Height	0.30 "
Contents, without containing cell	36 cub. decim.
Total weight without cell	50 kilogr.
Weight per kilowatt	330 "
" " kilowatt-hour	67 "
Volume " "	240 cub. decimetres.
" " " "	49 " "

Without mentioning the applications to the military art, there are many instances in which a horse-power-hour cell such as this would be of service, as, for instance, in the lighting of carriages, railway cars, and the propulsion of electrical pleasure boats, etc.

LIMITATION OF STREET RAILWAY FRANCHISES.

The city of Toronto, Can., has lately taken steps, under terms of a lapsing franchise, to acquire the local street railway property. The company has asked $5,500,000, but the city expects to pay only about $1,500,000. Last year the road earned net $250,000. Discussing the situation, the Chicago *News* says: "The streets of every city are the property of the citizens, and no corporation has a right to use them as private property. This usurped right is especially flagrant when the growth of population, as in Chicago, converts street railway monopolies into gold mines. Still more flagrant is the case of these monopolies arrogating such proprietary rights as to make war with the citizens on the questions of accommodations, reasonable fares, etc.

"Chicago needs to learn a lesson from other and less pretentious cities in the limitation of public franchises. Every ordinance giving street car corporations the right of extension should contain a clause limiting the life of a franchise to a reasonable term of years with the privilege of purchase by the city on its expiration at an arbitrated valuation. To those who may object to direct municipal control of street railways it need only be said that such direct control is not contemplated. The method prevailing in many English cities is for the municipality to retain the ownership of the tracks and real estate, leasing the rolling stock to the company that pays most for the privilege of operating the road. This is the method which will probably be followed in Toronto. It solves every objection, as the increment from the property goes into the city treasury instead of into the coffers of the corporation."

1. *L'Electricien.*

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—V.

BY HERBERT LAWS WEBB.

KEYS.

A form of *short circuit* key is shown in Fig. 18. As its name implies, the function of this key is to short circuit the galvanometer; being bridged across the galvanometer circuit, when the key is closed, a direct path for the cur-

FIG. 18.—SHORT CIRCUIT KEY.

rent is provided by the lever of the key and no current passes through the galvanometer; when the key is opened the galvanometer is thrown in circuit and the current passes through it. By the use of this key the galvanometer is protected from being violently deflected by the first rush of charge when current is turned on, and when a balance is being obtained in a resistance test with the dial bridge.

The form of key shown consists of a brass lever, hinged at one end, and playing in a brass bridge, having a metallic contact above and a stop of insulating material below. On the hard rubber pillar which supports the lever, and on the bridge, are placed double binding-posts to which the wires are attached. In its normal position the lever is pressed by a stiff spring against the upper contact, and forms a direct connection between the binding posts; by pressing it down the contact is broken, thereby removing the short circuit. A trigger attachment, mounted opposite the end of the lever, holds the key in the open position as long as may be desired.

A better form of this key than the one shown, is that in which, instead of the pivoted lever, a strip of springy brass is used, being held rigidly at the end fixed to the hard rubber pillar. With this kind of key there is no risk of imperfect contact through weakening of the spring, a very annoying defect to which the other is liable.

Besides these keys, which are indispensable, a very useful instrument on the testing table is a galvanometer reverser. It is often convenient to have all the deflections on the same side of the scale, and to effect this, when the battery is reversed, it is necessary to change the direction in which the current enters the galvanometer. To do this, any form of battery reversing key, such as those shown in Figs. 14 and 15, may be employed, but preference should be given to the double-plug switch shown in Fig. 19.

This consists of a circular plate of brass, divided into four quadrants, which are mounted on hard rubber pillars, rising from a base of the same material. Each quadrant is provided with a double binding-post for attaching wires, and two brass plugs, with insulating handles, serve for connecting the quadrants in pairs. This switch is connected in the galvanometer circuit, and the direction in which the current enters the galvanometer may be changed by simply altering the plugs. The plugs should have long stems, so that the hard rubber handles or tips may project clear above the binding-posts, giving greater convenience in handling than the short plugs used for resistance boxes and bridges.

RESISTANCE BOXES.

IN a complete outfit of testing instruments a high resistance for taking the constant of the galvanometer and a Wheatstone bridge for measuring resistances are absolutely necessary, and a box containing a number of coils having different resistances is a very useful addition.

The high resistance box generally contains four coils of 10,000, 20,000, 30,000 and 40,000 ohms resistance, making 100,000 ohms resistance in all. This instrument is illustrated in Fig. 20. The ends of the coils are brought to brass blocks on the top of the box, these blocks being provided with double binding posts and connecting plugs, so that the coils may be connected in any combination desired, although the most general manner of using the coils is all in series, giving the full resistance of 100,000 ohms.

High resistances are also made up containing ten coils of 100,000 ohms each, giving a total of one megohm. A megohm resistance enables the galvanometer constant to be taken with greater accuracy and allows of the galvanometer being adjusted to its maximum sensitiveness; but such a high resistance is very expensive, costing about seven times as much as a 100,000 ohm box. A firm of electrical instrument makers in England have lately brought out a high resistance box, containing a mixture of glass and metal, instead of wire; these instruments have to be calibrated after they are made, as it is impossible to give the mixture any fixed resistance. They generally have a resistance of several megohms, but rarely come out in round numbers, running, instead, to at least two decimal places. This is somewhat inconvenient in multiplying, but as an offset the instruments are very cheap, the price being about one-half that of a 100,000 ohm box. Given this advantage, and if the resistance remains reasonably constant with time and temperature, this form of high resistance box will no doubt find many users. I understand that it has already been adopted by several of the submarine cable companies.

The *Wheatstone bridge* is made up in a variety of forms,

FIG. 19.—DOUBLE PLUG REVERSER.

of which the most convenient are those known as the dial and the Post-office patterns. Both these styles have their advantages, the former being very easy to read and involving the handling of few plugs, while the latter is more compact and easier to manipulate, as the battery and galvanometer keys are permanently connected to the coils and form part of the instrument. Dial bridges are now being manufactured, however, with this convenience, the keys being placed in front of the dials similarly to the arrangement of the Post-office bridge.

The function of the Wheatstone bridge in the measure-

ment of resistances has already been explained and will be further treated of when we come to actual testing instructions, so that it will be sufficient here to describe the connections and plan of the instruments themselves. The dial form is illustrated in Fig. 21. The coils are arranged in sets of thousands, hundreds, tens and units; sometimes a fifth set of tenths of an ohm being added. The ends of the coils are brought to the brass segment blocks arranged around a circular plate of brass.

Starting from one end of the proportional coils connection is made to the zero segment of the end set of blocks; the resistance coils are placed between the segment blocks, one between 0 and 1, one betweeen 1 and 2, and so on, and the circular plate of each dial is connected to the zero segment block of the next, and so on throughout. Thus the number of the segment block connected by the plug to the circular plate represents the number of resistance coils in circuit, whether they be units, tens, hundreds, or thousands. The proportional coils terminate in brass blocks placed at one side of the adjustable resistance coils. These proportional coils form the two arms of the bridge or balance, and by altering their relation to each other the adjustable coils may be adapted to measure either very high, or very low, resistances. In the dial bridge the two sets of proportional coils usually consist of 10, 100, 1,000 and 10,000 ohms resistance. The battery current splits at the centre of the proportional coils, one part going through one set to the adjustable resistance coils, the other part going through the opposite set to the unknown resistance to be measured.

If the resistance unplugged in the proportional coils is the same on both sides, the readings obtained by the adjustable coils will be the actual value of the resistance which is being measured. If the resistance to be measured is very small we can obtain its resistance to three decimal places by unplugging the 10,000 ohm coil in the arm nearest the adjustable coils and the 10 ohm coil in the arm

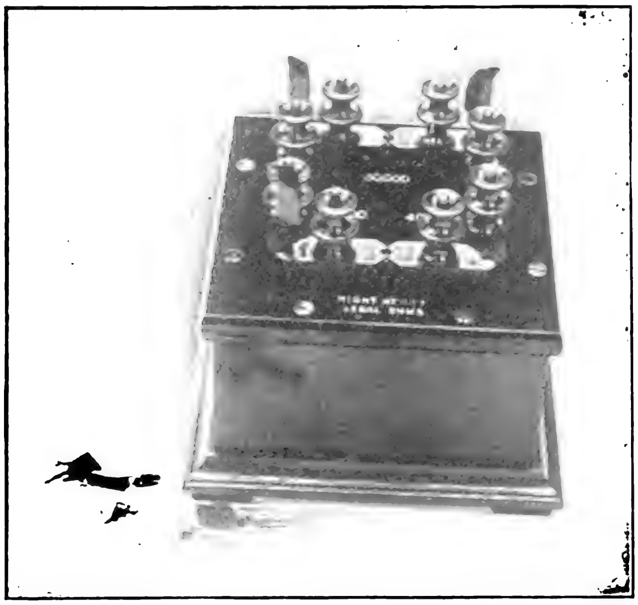


Fig. 20.—High Resistance Box.

to which the unknown resistance is connected. Then, as b (the resistance between battery and coils) is 1,000 times greater than a (the resistance between battery and unknown resistance), so d (the resistance in coils) is 1,000 times greater than x (the unknown resistance), and the reading obtained must be divided by 1,000 to find the true value of x.

In the same way, if the resistance of x is known to be much greater than the maximum value we can give to d while a and b are equal, then, by making a greater than b, the reverse is the case, and the readings must be multiplied by the ratio of a to b in order to find the value of x. With proportional coils of 10, 100, 1,000 and 10,000 ohms, therefore, the bridge has a very wide range, being capable of measuring from .001 of an ohm to 10 megohms. It must be borne in mind that some resistance must always be

Fig. 21.—Wheatstone "Dial" Bridge.

unplugged in the proportional coils, as otherwise the galvanometer, which is connected to their extremes, would be short-circuited.

OVERHEAD ELECTRIC LIGHT CONDUCTORS.[1]

The following illustrations, Figs. 1 and 2, represent three varieties of aerial conductors. No. 1 is that required by

1. *The Electrician.*

ELECTRICAL ENGINEERS.

RUDOLF EICKEMEYER.

Those who are in the slightest degree familiar with the course of electrical invention and improvement must have been impressed with the frequent occurrence and repetition of the name of Eickemeyer, and the impression gathered has doubtless been that, whoever Mr. Eickemeyer might be, he certainly was devoting himself to electricity in a very enthusiastic, thoroughgoing and successful manner. In point of fact the reputation that Mr. Eickemeyer has gained in electrical circles comes to him somewhat late in life, and is really but a pendant to that which has long been his in other fields of work. As proof of this, and putting aside other achievements to which reference will be made later, it may be stated that for 40 years he has been the most prolific inventor of hat making machinery and processes in America, his name being known to the hat industry all over the world.

R. Eickemeyer

Rudolf Eickemeyer was born October 18, 1831, in Bavaria, where his father was a forester. At the age of thirteen he left the village school, and attended the Real-Schule at Kaiserslautern, whence he removed in two or three years to the Polytechnic Institute at Darmstadt, where he devoted himself with much energy to the scientific and technical studies of the place. He made rapid progress, his tastes all lying in that direction, but it was destined that he should not gratify in peace his thirst for knowledge. The revolutionary fires of 1848 were breaking out with volcanic suddenness all over Europe, and from one end of the Continent to the other people rose in insurrection. This democratic movement was most intense and active in the smaller kingdoms and principalities where the few remnants of feudalism and medievalism became more irksome than the whole régime had once been; and the struggle for liberty of thought and action naturally enlisted at once a youth of so ardent a temperament. Still a mere boy, Rudolf, with his classmate George Osterheld—who afterwards became his business partner here—threw himself heartily into the fray, joined the "rebels," and fought under General Siegel. But the time was not ripe for revolt, the movement failed, and the suppression of the rebellion placed the participants in it in a very unenviable position. It is true that Eickemeyer and Osterheld were amnestied, but their future was darkened. Like others who took part in the risings in Germany at that time, they soon left home for America; and the two young men landed in New York, in November, 1850.

The Erie railroad was being built at that time, and Mr. Eickemeyer found employment on it at Lodi. The year after, 1851, he secured a position at Buffalo, in the Buffalo Steam Engine Works, his duty being to assist in making the first mowing machines produced in this State. In 1854, he established himself at Yonkers, in association with Mr. Osterheld, in the business of repairing the tools used in the hat shops and other factories of that busy little city on the Hudson. The work at first was wearisome and ill paid, but a footing was soon gained, and a start was made for which Mr. Eickemeyer has since repaid Yonkers many times over.

It was now that his inventive genius first began to display itself effectively. He had long been a master of the principles of mechanism, but he had never before been thrown into close contact with a growing industry hampered by the crudity of its productive apparatus. He now had the direct appeal made to the practical side of his imagination, and in a very short time he began the course of invention which has since practically re-created the art of hat making as practiced in America and abroad. It would be foreign to our purpose to speak of his improvements in this industry in detail, but we may say that they include every detail and are embodied in hat blocking machines, hat shaving machines, stretchers, blockers, formers, presses, ironing machines, sizing machines, sewing machines, fulling mills, machines to pounce hats in a cone shape, and a variety of others, automatic in operation, and exhibiting the greatest ingenuity in substituting the operation of mechanism for slow, laborious and costly methods of hand production. The factory for the manufacture of such machinery was built at Yonkers, in 1865, and has since that time been kept in active operation with a large force of skilled machinists.

At the beginning of the civil war, Mr. Eickemeyer was quick to see the opportunity of using his hat sewing machine tools in the manufacture of firearms, and thereafter for a number of years large quantities of revolvers were made at Yonkers, as a distinct department of the busines. In 1869 and 1870, Mr. Eickemeyer invented and perfected a driving mechanism for mowing machines, which proved to be extraordinarily simple and smooth running, and which, when exhibited at the Centennial Exposition, was awarded a bronze medal for its lightness of draft. It should be added that three other bronze medals were awarded Osterheld and Eickemeyer at the same time for their exhibit of hatting and other machinery. The mowing machine referred to has since been manufactured on an extensive scale at Springfield, O., and in a modified form as a one-horse mower, by a firm in Yonkers.

The above recapitulation of Mr. Eickemeyer's work, is, as will be seen, the merest outline, but it will suffice to justify the remark made at the beginning of this biographical sketch to the effect that his electrical work has been but a corollary to his remarkable inventions in other branches, represented by not less than 150 patents, some of which are of great value. If our readers desire to see what is thought in the hat trade of his work, we may refer them to a most interesting and instructive article published by the New York *Hat, Cap and Fur Trade Review*, in August, 1882.

Mr. Eickemeyer had always followed in a general way

the various advances in the sciences, taking great interest in electricity, and when the Bell telephone was brought out, having more time and means at his disposal than he had previously enjoyed, he took up electricity as a study for his leisure rather than with a view to apply it in a practical way. Experimenting with various forms of telephones, he became familiar with the peculiarities of different forms of electro magnets, and from their use in telephones to the construction of dynamos was but a step. The celebrated ironclad dynamos and motors known as the "Eickemeyer" were the first attempt on his part to put to practical use the results of electrical studies and investigations extending over a space of nearly ten years. They have proved very satisfactory, and their operation under a variety of conditions during the last three years has shown them to be electrically and mechanically the equal of the best known machines in the market. Dynamos of this type have been built, varying in output from 2,500 volts and 10 amperes to 5 volts and 500 amperes, and the results have been gratifying in all cases, but perhaps most so in train lighting, where the solidity of the machine has been of great service. Although some 25 machines have been employed in this trying work, not a single armature has been burned out or in any way injured.

The Eickemeyer motor has also been applied to electric railway work, and found highly efficient. The construction of a slow running motor, coupled directly to the driving shaft of a street car, seems to open up a new field and mark a new departure in electric traction, as it avoids the use of gearing, which is still the weak point and bugbear in street railway work. It deserves mention here that the Edison system has adopted the Eickemeyer winding for its railway motors.

The question of the best material to be used in the construction of dynamos caused him to set to work to get some instrument which would enable him to determine readily the relative values, magnetically, of various qualities of iron and steel; and the result was a magnetic bridge, by means of which the magnetic value of the material can be told as readily as a loaf of bread is weighed on the scales of a bakery. The instrument has proved a complete magnetic laboratory in itself, and by its use Mr. Eickemeyer has been able to determine many questions in the construction of electric devices, which, without it, would have been difficult and expensive experiments.

Mr. Eickemeyer has also done some very interesting work in connection with the storage battery and the alternating motor, and in the latter respect his work is surprisingly early, anticipating it would seem, by years, many of the machines lately put forward as startling novelties. He is as active, too, in electrical work to-day as he has ever been, and far more than the Patent Office files would indicate, it being his invariable practice to build and run every new machine before patenting it or the principles it embodies.

Mr. Eickemeyer was married in 1856 to Miss Mary T. Tarbell, of Dover, Me., and the eldest of his six children, Rudolf Eickemeyer, Jr., is now a member of the firm. Mr. Eickemeyer, has, unlike the majority of well-known inventors, found time for the performance of various public duties, and has rendered conspicuous service on the Yonkers School Board and Board of Water Commissioners. Our portrait of him, recently taken, is very faithful and characteristic.

SEPARATING COPPER FROM ARSENIC.

If the current of four or five cells is passed through an arseniate solution, rendered alkaline by means of ammoniac, no separation or reduction of the arsenic acid takes place; but if a solution of copper salts is so treated, there is a complete separation of the copper. This difference of action has, according to *Electrotechnische Zeitschrift*, been utilized to separate arsenic from copper. The experiments were made with solutions prepared beforehand, and after 24 hours it could be ascertained by weighing that all the copper was deposited.

THE ELMORE PROCESS OF MAKING METAL TUBES BY ELECTRO-DEPOSITION.

The process of producing metal tubes by electro-deposition as practiced in the Elmore process has recently been patented in this country by Mr. Francis Edward Elmore, of Cockermouth, England. As the process is just now attracting considerable attention abroad, and may be shortly introduced in this country, we give in the accompanying

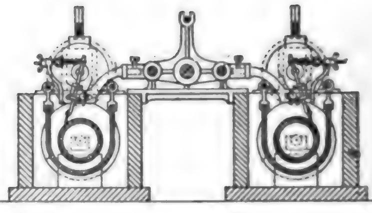

Fig. 1.—The Elmore Copper Depositing Process.

engravings, Figs. 1 and 2, an idea of the plan adopted for obtaining the metal tubes of tough copper.

The latter quality is obtained by burnishing the surface of the deposited tube or other article during the time at which the deposit is going on in the tank. The core or mandrel to receive the deposit is mounted in the tank by its axle, and upon the side of the tank are mounted guides, and a traveler fitted with worm and change motion for traversing the traveler to and fro over the tank.

The traveler has a carrier attached, upon which are mounted burnishing-surfaces, such as agates or glass having a highly-polished surface—that is, a non-conducting

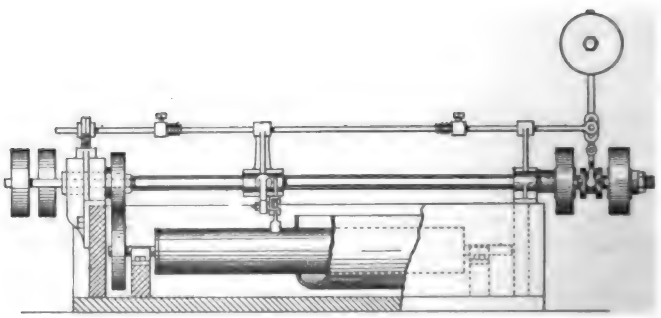

Fig. 2.—The Elmore Copper Depositing Process.

substance capable of burnishing and which is not acted upon by the electrolyte. The burnisher operates upon the surface of the deposited metal and a continuous motion of rotation is given to the core or mandrel receiving the deposit.

HINTS OF COMING TELEPHONE OPPOSITION.

With regard to the proposed cutting down in Utica, N. Y., of the unused wires of the Baxter Overhead Telegraph & Telephone Co., Mr. T. J. Griffiths, treasurer of that company, objects and says: "The wires are disconnected at both ends and could not lead a current to any point where it could do damage. It would be a great injustice to cut down these wires, for the Baxter company intends using them again, as soon as the Bell patents expire in 1893. The government has 300 instruments belonging to the company, stored in the government building; the batteries and all apparatus necessary to the business are intact and we shall be ready to do business within three months after the expiration of the patents. We shall furnish telephones at one-third the rental charged by the Central New York Company, with rebates according to the number of instruments used. The Baxter company owes between $6,000 and $7,000, and a few of us have been carrying it along with the intention of starting up again in 1893."

Sioux City, Ia.—The reconstruction of the Western Union's telegraph lines between Dubuque and Sioux City, a distance of 320 miles, has just been completed. A new wire has been run from Fort Dodge to Sioux City, and another from Le Mars to Sioux City. During the next month three new wires will be run between Dubuque and Sioux. The whole line is built of copper wire on 35 foot poles.

THE TOMMASI MULTIPOLAR STORAGE BATTERY.

The new system of accumulators invented by Dr. Donato Tommasi, of Paris, is distinguished by the peculiar form of the electrodes which are employed in place of the usual plates. The accompanying engraving, Fig. 1, shows the cell partly broken away, exposing the interior. Each electrode is formed of a perforated tube or folded sheet closed at one end by a small plate of insulating material into which is screwed a rod, as shown in Fig. 2, which shows one of the electrodes enlarged. The rod, which serves as a support for the tube electrode, is provided with a suspension head, which also serves as a contact. Instead of cylindrical tubes prismatic ones may be employed, as shown in Fig. 3, which utilize the space in the cells somewhat better than the former.

The grouping of the electrodes may be done in different ways, in lines or series, alternately positive and negative. The electrodes of one line are suspended by their heads in slots in the cover of the cell, and are introduced into the large aperture at the end of the slot and slid into place. In each accumulator the conductors which are let into the cover and upon which rest the electrodes of like sign are interconnected, as shown, so that the cover is provided with only two terminals, positive and negative.

In the annular space between the tube and the central conductor of each electrode the active matter, spongy lead or lead oxide, etc., is packed, so that the tube serves only as a support for such matter and can be made of any substance desired, so long as it is not attacked by the acid. Up to the present, lead and antimony-lead alloy have been used for these tubes, and the central rods have been given various shapes to increase their surface.

Among the advantages claimed by Dr. Tommasi for

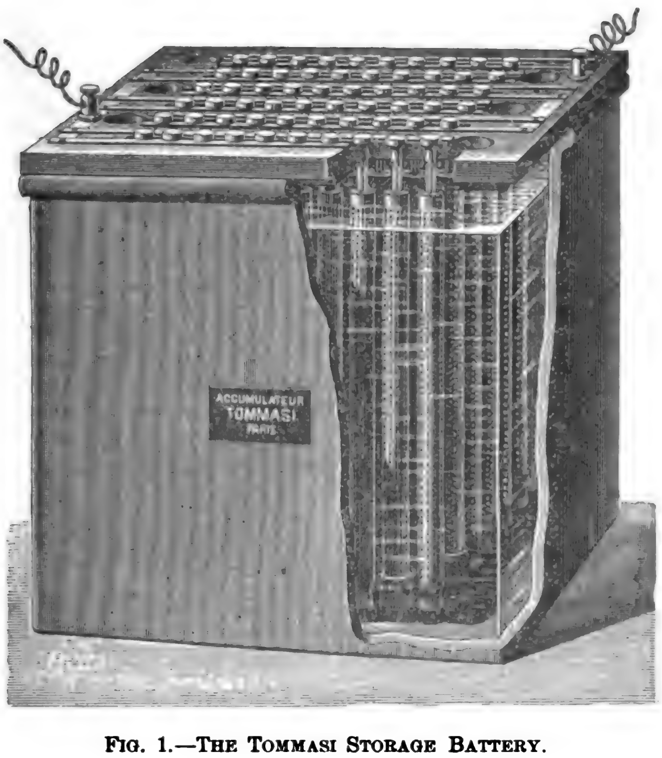

Fig. 1.—The Tommasi Storage Battery.

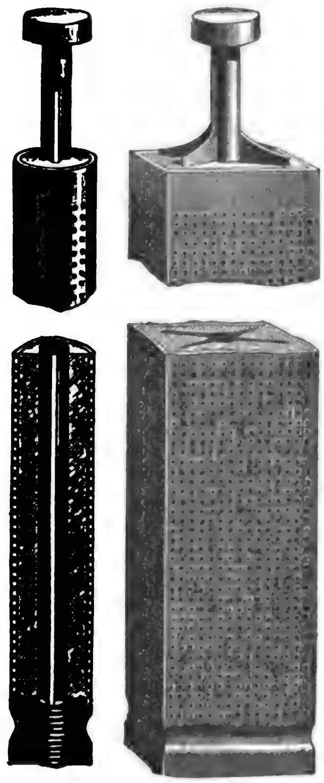
this type of cell are that the current passes entirely across the active material from the surface of the tube to the central rod, and *vice versa*.

For the formation of the electrodes very heavy currents can be employed without fear of loosening the material or of buckling the electrodes. The quantity of active material is made a maximum by the arrangement in tubes. On the other hand the chemical action of the current is uniform throughout the mass. As a result it has been possible to send currents of from 50 to 60 amperes per kilogram of electrode without involving the slightest displacement of the contents of the tubes. Of course these are not the conditions of actual practice, as with such heavy currents there is a heating of the entire mass; but the experiments prove that, practically, one can go very far beyond one ampere per kilogram, the usual rate of discharge in the ordinary type of cell. The multipolar accumulators having no soldered joints, no rupture need be feared and the electrodes can be removed one by one, even during the operation of the cell. The arrangement adopted also makes the cell very easy of transportation.



Figs. 2 and 3.—The Tommasi Storage Battery.

1. *La Lumiere Electrique.*

PRICES OF LIGHTS AND SUBWAYS IN NEW YORK.

The Gas Commission has rejected all the electric light bids submitted for street lamps. Should the 1,386 arcs be displaced, no fewer than 30,000 gas lamps would be required. It is hardly likely, however, that the commission will be precipitate in the matter.

In the meantime, the Consolidated Subway Co. has been prevented from turning over part of its work to the Empire City Subway Co., the Board of Electrical Control being enjoined from relieving the old company of any of its obligations. As a retaliatory measure, the Mayor has caused the subway rental rates to be fixed at $900 for 3-inch duct per mile; $800 for 2½-inch and $700 for 2-inch. The former rates were $1,000, $850 and $750. These rates are not satisfactory to the electric light companies.

BROADWAY AND NEWBURGH ROAD, CLEVELAND, O.

The Broadway and Newburgh road reports increase of its capital stock from $500,000 to $1,000,000. Its officers are Horace E. Andrews, president; John J. Stanley, vice-president and superintendent, and Edwin Fowler, secretary and treasurer. The company is operating its road on the Edison overhead system. It has 25 miles of track laid with the 82 lb. Johnson girder rail, and has 25 motor cars with 47 trail cars. The cars are of the Brill make. The Edison generators are run by three 300 h. p. engines from E. P. Allis & Co.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. X. NEW YORK, DECEMBER 17, 1890. No. 137

The neglected borderland between two branches of knowledge is often that which best repays cultivation.—Lord Rayleigh.

PRICES OF ELECTRICAL APPARATUS.

THE recent reductions in the price of electrical manufactures have already attracted some attention but not by any means that which they are likely to receive when the present financial stringency and disturbance settles back into normal conditions. The changes that affect a whole industry are necessarily of great interest, and they become the more important if they are of such a nature as to cause a radical and permanent readjustment of the market all along the line. The question that arises and becomes vital is: Are these lower prices abnormal, and of short duration, or are they to continue steadily so that every future arrangement must be made on their basis?

A brief editorial discussion of the prices of electrical goods in the *Boston Commercial Bulletin* shows us that the situation is not fully understood, even by such an authority on commercial and industrial subjects. Taking the recent reductions of price on Edison lamps and motors, it says: "If a reduction of 50 per cent. will leave them still a profit which they call that of a manufacturer, heretofore their profit on apparatus must have been over 100 per cent., and as all the companies sold electrical machinery for about the same list price, they must have all made approximately the same profit. The question now is what will the other companies do? Will they reduce their prices to meet the competition or lose business? As yet we hear of no large or even fair-sized company, making a reduction and we shall be obliged to wait for further developments. It seems as though we were to commence an era of lower prices for electrical apparatus. Prices have been reduced from time to time in the past and there still remains room for further reductions. It is an undeniable fact that years ago when the Brush Electric Co., of Cleveland, O., controlled the manufacture of electrical apparatus in this country, the company made over 300 per cent. profit on its dynamos, and competition gradually brought this profit down to its present basis." Now, it does not follow that the net profit heretofore has been either 100 per cent. or 300 per cent. It is to be remembered that during the ten years past, in which the electric light and power industry has taken shape, vast sums have been expended in experiments, patents and litigations. Those items of outlay have had to be counterbalanced, and hence almost up to the present moment, electrical manufacturers, especially the leading pioneers, to remain solvent, have had to figure them in their estimates of the cost of production, with a further allowance for the risk of the particular invention being superseded by something better that they do not control. In other words, electrical manufacturers have often not known what it cost them to make their product, and while prices have seemed high it has been evident after a time that they were actually not high enough if the business was to be carried on at a profit.

To a very appreciable degree, however, the electric light and power business has released itself from these earlier conditions, which constituted such an enormous tax on its earnings, and to-day the general position is as near that of a simple manufacturing industry as it is possible for anything so young and new to be. There is no necessity, then, to offer as an explanation, as the *Commercial Bulletin* does, that the Edison reduction has been made either to get free advertising, or to raise ready money, or to meet the competition of "a great many small companies that have started in the West to manufacture lamps and at a lower price." These, surely, are gratuitous assumptions in view of the regular tendency to reduction that has been seen for years. We have also heard it said that the reduction is largely due to the personal views and influence of one of the leading officials of the Edison Company. But even if that were true, as it well may be, it would only mean a readier perception in some quarters than others, in that company, that if Mr. Edison's intention of making "electricity as cheap as gas" were to be carried out, apparatus must be continuously made cheaper to the consumer, whether in central station or isolated plant. Gas and all its appliances are made better and cheaper than they were ten years ago, and certainly the evolution in electricity in becoming a staple necessity for the masses must be no slower. So far, then, from being casual or spasmodic, we take it that these reductions made by the Edison Company on one or two articles, are but the expressions of a well-defined, far-sighted policy that will not rest until its every product has been rescaled by the cost of its manufacture and the extent of an expanding market.

On the whole, therefore, we do not think that any action on the part of the great companies in lowering prices, as all of them have done at one time or another, need be explained by special causes or be looked upon with despondency. An experience of not a few years in this field teaches us that every reduction of a legitimate nature has been quickly responded to by a vastly enhanced demand. At the present juncture, the general contraction of business throughout the country, even though it be temporary, would have been accompanied by a check in electrical

growth, and this in turn would have limited sales, with consequent loss to both capital and labor. We are now very much inclined to doubt whether such restriction will be seen, and the tendency with lower prices is exactly in the opposite direction. In electric lighting, cheaper lamps will prove a stimulus, and the production of current, the main work of a central station, will be cheapened, with a brisker call for stationary motors. In street railway work, where already "electricity" is a synonym for "economy," there will be no falling off, with cheaper motors and generators; and our columns every week exhibit proof of the rapidity with which that department is growing. In short, amid all the unnecessarily higher and false prices that result from recent unwise tariff legislation, it is a pleasure to see that the electrical industries face the situation with firm values and on more solid ground of vantage than ever before.

THE LAW OF HYSTERESIS.

In the design of all alternate current apparatus, and especially in transformers, the loss due to hysteresis enters largely into the calculations, and is, indeed, the determining factor in the design of the modern transformer. The curves of Ewing have exhibited and proved in a graphic manner the rapid rise in hysteresis with increase in the density of magnetization, which has limited constructors of alternating apparatus to the use of magnetizing forces far below those generally employed in continuous current work. Up to the present, however, the law expressing the ratio of loss by hysteresis in terms of the magnetization has not been the subject of investigation, and hence the work of Mr. Steinmetz on this subject, appearing in our columns this week, deserves special attention. By subjecting a large number of observations of Ewing to analysis, Mr. Steinmetz finds that the loss by hysteresis may be very approximately expressed as varying in the ratio of the 1.6 power of the magnetization. The agreement between the observed and calculated values, as found by the law enunciated by Mr. Steinmetz, is so close that there appears to be little doubt left as to its accuracy, up to the limits, at least, of Prof. Ewing's observations.

INVENTING MADE EASY.

A paper of a very interesting nature—like all of those before the New York Electrical Society—was that by Mr. E. P. Thompson, of which we present an abstract in this issue. Mr. Thompson has long given special thought to questions of invention, in addition to those of patents, and his paper embodies a number of valuable hints and suggestions. While he does not claim that inventing can be made easy, he does assert that the gift of invention has been pretty liberally bestowed by nature, and that if some are endowed prodigally with the inventive faculty, others can develop their lesser talent up to the point of practical utility. The need of education and training is wisely emphasized. Very few, if any, instances of great inventions can be cited as being made by ignorant men, haphazard. The element of what we call chance may come in, but it is not determining. It was "chance" that took to Yonkers Mr. Eickemeyer, whose biography we publish this week, and chance, too, that led him to a study of hat making machinery. But he was already master of the principles of mechanism, and would as readily have invented in the paper making industry, had chance thrown him there.

Would-be inventors will do well to heed Mr. Thompson's advice to study the technical papers regularly. It will save them from much waste of time and money, and much re-inventing. It will also inform them of the lines of invention that are being most actively pursued. But they should seek out new fields for themselves. Inventors with all their originality are often like so many sheep, ready to follow any lead, whereas the fact that one master mind is exhausting any given department should be, primarily, a caution to let it alone. In electricity there is to-day abundant room for every inventor. It is all opportunity.

Storage Battery Work.

Notwithstanding the large number of modifications which the storage battery has undergone in detail of construction to adapt it more conveniently to particular purposes, or to increase its efficiency and durability, new forms are continually cropping up to demonstrate that there is still a field for profitable employment of inventive genius here. As evidence of this, we need only refer to two types of battery illustrated in this issue. In one of these, M. Reynier, working in the same lines as Mr. Dey, whose battery we described recently in these columns, provides in a single cell a combination having a difference of potential of 32 volts, and possessing in a high degree the properties of elasticity and freedom of motion of the plates without injury. In the other case Dr. Tommasi secures immunity from buckling, together with several other advantages, by dividing each plate, as it were, into a series of elements, which can be easily removed and inspected at any time. The data regarding the latter cell is still lacking, so that no comparison can yet be made between it and the other forms now existing. There seems also to be some room for improvement in the nature of the contact between the individual elements and the conducting strips at the top of the cell.

Slow Speed Motors.

There is an unmistakable tendency to the application of electric motors of a speed lower than that which has been generally employed up to the present. The reasons for this are apparent when we consider the fact that under ordinary circumstances a countershaft is required to transmit power from the high speed electric motor to the working shaft. For such work evidently the multipolar motor offers an easy solution, and it has been availed of recently by a number of well-known constructors. Among others Mr. A. L. Riker, whose motor he describes himself in another column, has devoted considerable attention to this department, and as a result he has combined in his machine a variety of novel features. The cross-connection of the segments of the commutator within the body of the same is a feature worthy of attention, as well as the general compact design of the machine. It will be noted also that Mr. Riker employs a toothed armature. Many modern designers are returning to this older type, which, at one time almost entirely discarded, is again coming into use with good effect, helped by the improvements effected as the result of experience.

JONES' MAIN OFFICE TELEGRAPH CIRCUITS.

In main telegraph offices where dynamos are employed as the source of current, it is very desirable to make speedy connection between the sending and receiving apparatus of a quadruplex or duplex system situated in the main office and the sending and receiving apparatus in a branch office

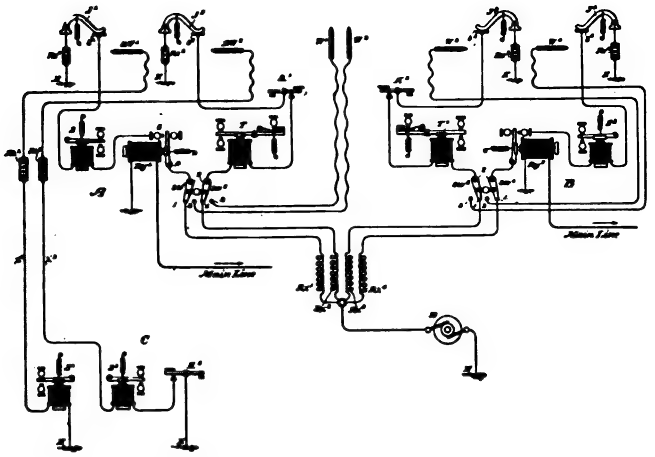

FIG. 1.—JONES' DYNAMO MAIN AND LOCAL CIRCUIT.

so that the operator in the branch office may be able to send signals through, and receive signals from, the quadruplex or duplex circuit as easily as if he were situated in the main office. To effect this and to admit of the easy and rapid connection of a single Morse circuit with a quadruplex or duplex circuit, as well as the automatic transmission of messages simultaneously from one duplex circuit to another, Mr. Frank W. Jones, the well known electrician and general manager of the Postal Telegraph Cable Co., has designed and put in operation the arrangement illustrated in the accompanying diagrams.

In Fig. 1, A and B indicate, respectively, two sets of duplex apparatus, or one duplex set and one side of a quadruplex set located in the repeating or main office, in their normal condition. C shows the receiving and sending apparatus at a branch office.

Assuming the dynamo D to have a potential of thirty volts and the local circuit *via* Rx', b', and J' a resistance of one hundred and fifty ohms—composed as follows, Rx', thirty ohms; S, twenty ohms; Re' and the other parts of

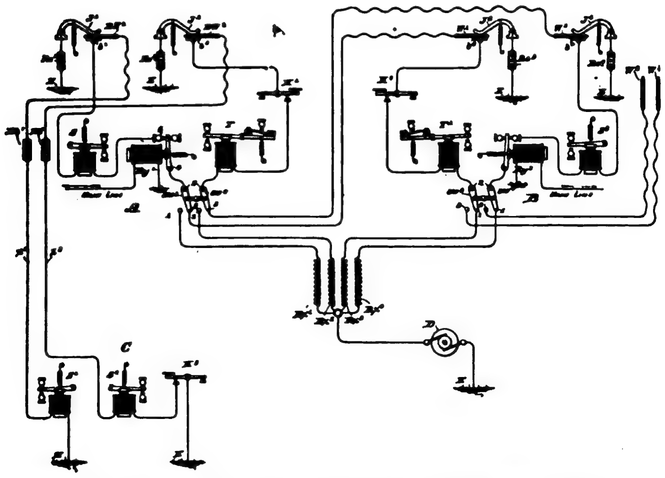

FIG. 2.—JONES' DYNAMO AUTOMATIC REPEATER CIRCUIT.

the circuit, one hundred ohms; total, one hundred and fifty ohms—then the electro-magnet S will be energized by a current of two hundred milliamperes when Ry' is closed at point 5, and similarly in respect to the other circuits *via* Rx^2, Rx^3, Rx^4. Should BW' be inserted between J' and the plate b', the movable part of J' and the resistance Re' will be thrown out of circuit by the insulated side of BW' and a new circuit will be established *via* b', the conducting side of BW', rheostat Rh' and wire x' through branch-office apparatus C to earth. It is obvious that if the resistance of Rh', wire x', and sounder S is additively equal to resistance Re', then the current flowing from the dynamos *via* Rx', S, and BW' to branch office C will be equal to two hundred milliamperes, and the electro-magnets now in circuit will be energized by the same strength of current as was S of the main office prior to the insertion of BW', and similarly of all the other local circuits shown.

In case it is required to connect the local circuits of set A with those of set B to form an automatic repeater, it is only necessary to turn the three-point switches sw' and sw^2, Figs. 1 and 2, of set A to the right, connecting the points 2 and 3, and then inserting wedge W' in spring-jack J^3 and W^2 in J^4, when the proper arrangement of circuits will be established, as follows: A circuit will be formed from earth *via* the dynamo D, Rx^3, sw^3, T', key K^2, contact-plate b^3, wedge W', *via* flexible cord to sw', points 3 and 1, thence *via* points 4 and 5 of Ry', sounder S, contact-plate b' J', and resistance Re' to earth, as shown in Fig. 1. In Fig. 2 the circuit above described is continued through wedge Bw' of flexible cord Rh' and x' to branch office and earth, instead of *via* Re' and earth, when BW' is not inserted. A similar circuit to that above describedwill be established *via* Rx^4,

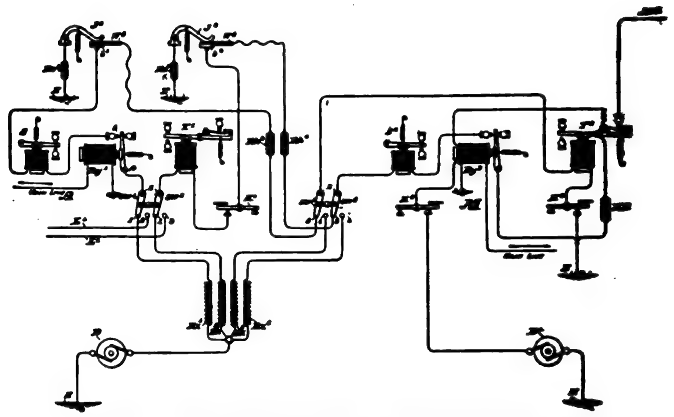

FIG. 3.—JONES' DYNAMO LOCAL DUPLEX CIRCUIT.

sw^4, Ry^2, S^3, b^4, and W^2 of set B, connecting with set A *via* flexible cord and sw^2, as will be readily understood by inspection of the diagrams. The resistance of these circuits as connected up in Fig. 2 will be somewhat greater than that previously assumed for various parts of the circuits, and the working-current will be less than before the insertion of W' and W^2, yet not sufficiently so as to render the electro-magnets inoperative.

Fig. 2 more clearly shows the connections described for the operation of sets A and B to automatically repeat into each other's main-line circuits through the mutual control of their local circuits, and the extension of their local circuits to earth at branch office C is shown on the left hand side. The dynamo circuits *via* Rx' and Rx^2 are shown open at sw' and sw^2, and the resistances Re', Re^2, Re^3, Re^4, are removed from their normal circuits by the insulated portion of the wedges.

Fig. 3 illustrates the apparatus and the necessary local connections employed for placing a single Morse circuit in connection with a duplexed circuit, or with one side of a quadruplexed circuit, at a repeater-station, so that the distant operator of the duplexed or quadruplexed circuit on one side of the repeater-station is enabled to transmit and receive messages to or from any station on the single Morse circuit on the other side of the repeater-station. During the time of the connection of the single with the multiple circuit, but one transmission of signals is possible either from the single circuit to the multiple circuit, or vice versa.

The single Morse circuit M L at M is shown in the diagram connected locally with a duplex set of apparatus at A in such a manner as to be capable of receiving signals from the duplex relay RY′ and of transmitting signals *via* the transmitter T of the duplex set without interference of one with the other in the well-known way. It will be understood that the distant operator on the duplex circuit keeps his key closed when desiring to receive signals from a Morse station on the single circuit in order that relay RY′ at A, Fig. 3, will remain in a closed position to hold transmitter F^3 closed to preserve the continuity of main line M L.

To restore the sets A and M to their normal or non-repeating condition it is necessary to remove W^5 and W^6 from J′ and J^2 and turn the three-point switches sw^5 and sw^6 to connect with their points 1 1 on the right. The local circuits of the single-line repeater M will then be supplied by currents from dynamo D *via* resistances Rx^5, Rx^6, as will be readily seen.

WOOD'S ELECTRIC METER.

Of the numerous principles applied to the purpose of an electric meter device, the heating property of the electric current has long been a favorite one, perhaps the best known meters in the class being the oscillating one of Prof. Elihu Thomson and that of Prof. Forbes. More recently Mr. J. J. Wood, the well known electrician now associated with the Fort Wayne Electric Co., has constructed a meter in which this principle is utilized in a very simple manner.

The engraving, Fig. 1, shows a front view of the meter, the construction of which will be readily understood from the diagram, Fig. 2. As will be seen, two very thin metal strips of fine wire A and A′ are rigidly fastened at the upper ends *a a* and at their lower ends to the short arm of

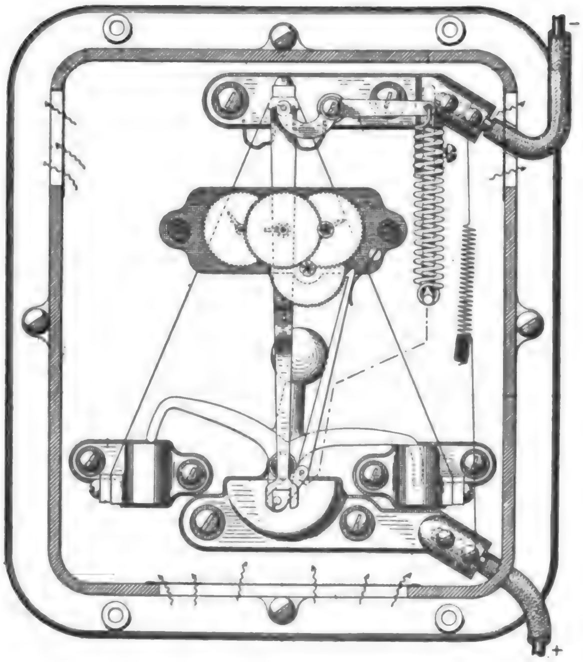

Fig. 1.—Wood's Electric Meter.

the lever B, the long arm of which terminates in a fork *c*′. The strips are maintained taut by the spring C, through the medium of the lever K.

The metal strips A A′ constitute high-resistance conductors for the electric current. They constitute also thermo-expansion devices, which by their differential expansion or contraction impart motion to the lever B. Thus, if an electric current of sufficient volume be sent through one of the strips—say, for example, the strip A—without being sent through the other, that strip will be heated by the current and will expand, while the strip A′, not being heated, will remain unchanged in length. The elongation of the strip A will relax the left-hand side of the short arm *b* of the lever, so that the tension of the spring C, acting against the middle of this boss, will tilt the lever and carry its arm *c* toward the left. The strip A′, thus constitutes a support for receiving the reaction of the lever, the

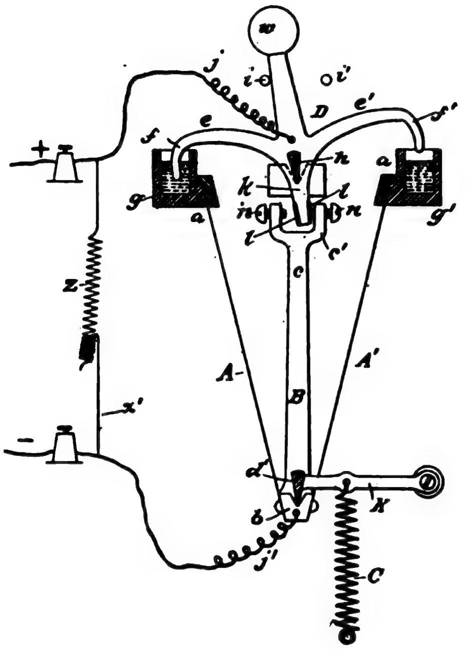

Fig. 2.—Wood's Electric Meter.

point of connection of its lower end with the right-hand side of the boss constituting for the moment the fulcrum on which the lever turns. The deflection of the lever will be directly proportional to the elongation of the strip A due to the heating effect of the current, since the strip A′, which is not heated by the current, is exposed to the same surrounding temperature as the strip A, so that whatever expansion or contraction is due to variations of external temperature or weather affects both strips A and A′ equally. The strip A′ thus becomes a compensating thermo-expansible support for receiving the reaction of the lever.

If upon the strip A reaching a certain temperature or having become expanded to a certain elongation the electric current is shunted through the strip A′ and cut off from the strip A, the strip A′ will become heated by the passage of the current and the strip A will simultaneously cool by radiation. The resulting expansion of the strip A′ and the contraction of the strip A will effect an oscillation of the lever B in the opposite direction, its arm *c* being deflected toward the right. Upon a certain deflection being reached the current can be again shunted back to the strip A, thereby again reversing the operation.

There results from these alternations in the path of the current a back-and-forth vibration of the lever B, which is utilized for imparting motion to the switch, by which the alternate shunting of the current is effected. These vibrations of the lever B occur with a frequency approximately proportional to the varying strength of the current, and they are utilized for the purpose of operating the recording or totalizing mechanism, which accordingly affords a correct indication of the total current which has traversed the instrument during a certain time.

The switch which effects the alternations in the current is quick acting and as an additional safeguard against arcing upon the change of current in the C strips, contact in one mercury cup is made before that in the other is broken.

NEW FORT WAYNE PRIMARY FUSE BOX.

One of the first requisites in any attachment to an electric circuit carrying a high tension current is safety in handling, especially in that class of apparatus which from its nature is apt to require attention at more or less frequent intervals. Among the latter the fusible cut-outs

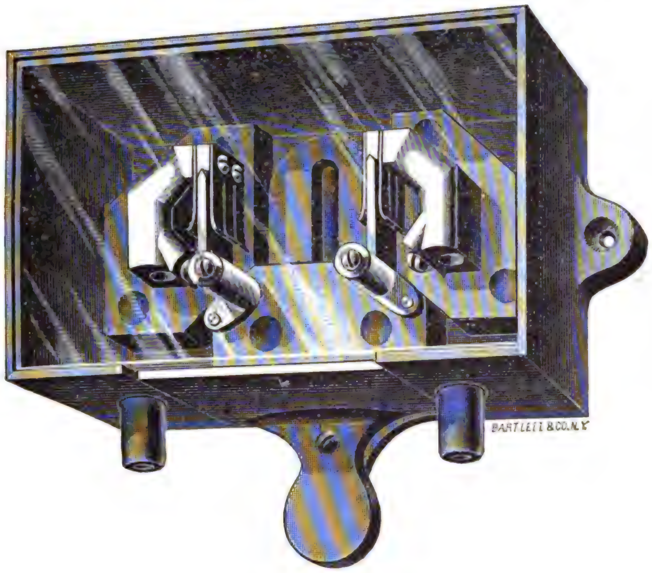

Fig. 1.—New Primary Fuse Box.

frequently require replacement when they have been blown, and when in circuit with high tension wires the arrangement ought to be such that the fuse can be replaced without danger to the attendant. In seeking to secure such safety the Fort Wayne Electric Company have recently

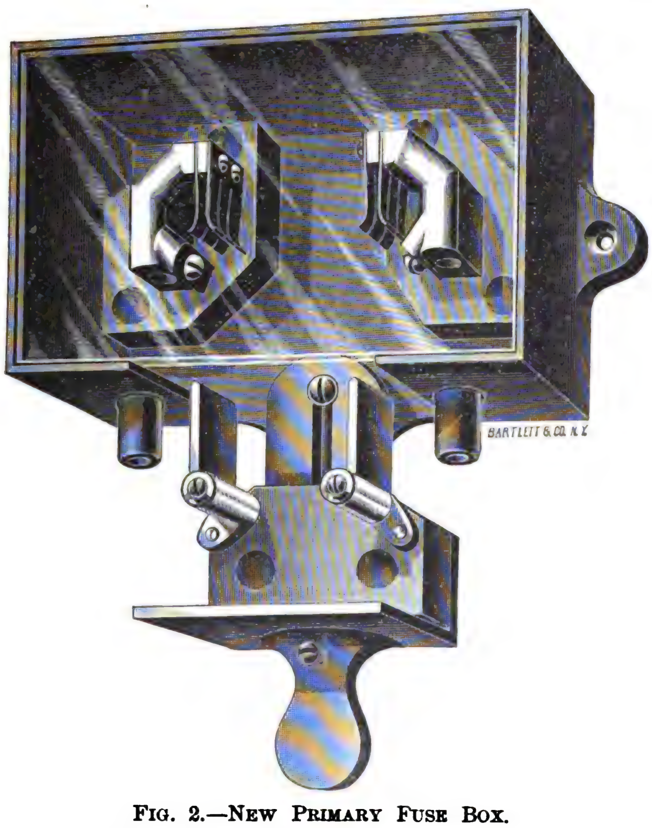

Fig. 2.—New Primary Fuse Box.

brought out the primary fuse box illustrated in the accompanying engravings.

As will be seen in Fig. 1, it consists of a cast iron box covered with a glass plate. The circuit, which enters from below through insulating bushings is connected to binding posts provided with spring clips. Between these clips two tongues make contact and thus close the circuit through the fuse wire. When a fuse blows, the attendant, by releasing the screw shown in the handle at the bottom, frees a slide which, upon being pulled out, withdraws the tongues from between the spring clips and thus breaks the circuit at two points. He is then enabled to insert the fuse with perfect safety and when finished pushes the slide back into place, which automatically restores the continuity of the circuit.

It will be evident that by this arrangement the replacing of the fuse cannot be accomplished without first breaking the circuit, so that entire immunity from accident is insured.

MAGNETISM AND RECALESCENCE.[1]

BY J. HOPKINSON, D.SC., F.R.S.

In my experiments, the results of which are published, "Phil. Trans." 1889, A, p. 443, I showed that recalescence and the disappearance of magnetizability in iron and steel occurred at about the same temperature. The evidence I then gave was sufficiently satisfactory, but did not amount to absolute proof of the identity of the temperatures. Osmond has shown that the temperature of recalescence depends upon the temperature to which the iron has been heated, also that it differs when the iron is heated and when it is cooled. He also showed that for some sorts of steel the heat is liberated at more than one temperature, notably that in steel with 0.29 per cent. of carbon, heat is liberated when cooling at 720° C. and at 660° C., and that with steel with 0.32 per cent. carbon there is a considerable liberation of heat before the temperature is reached when this becomes a maximum. It appeared to be desirable to obtain absolute proof that the change of magnetic property occurred exactly when heat was liberated and absorbed, and to examine, magnetically, Osmond's two temperatures of heat liberation. I have not been able to obtain samples of steel of the size I used, showing two well marked temperatures of heat liberation and absorption, but I have a ring in which there is liberation of heat extending over a considerable range of temperature.

The samples had the form of rings. A copper wire was well insulated with asbestos, and laid in a groove running round the ring, and was covered with several layers of asbestos paper laid in the groove. This coil was used for measuring temperature by its resistance. The whole ring was served over with asbestos paper and with sheets of mica. The secondary exploring coil was then wound on, next a serving of asbestos paper and mica, and then the primary coil, and, lastly, a good serving of asbestos paper was laid over all. In this way good insulation of the secondary coil was secured, and a reasonable certainty that the temperature coil took the precise temperature of the ring, and that at any time the ring was throughout at one and the same temperature. The whole was placed in an iron pot, and this again in a Fletcher gas furnace. Observations were made of temperature as the furnace was heating, and from time to time of induction. In each case the time of observation was noted. Similar observations were made as the ring cooled, the furnace being simply extinguished. We are thus enabled to compare directly at the same instant the condition of the same ring as regards magnetism and as regards temperature, and, therefore, qualitatively as regards its absorption or liberation of heat.

These experiments show that the liberation and absorption of heat, known as recalescence, and the change in magnetic condition, occur simultaneously. Also that in the case of steel with 0.3 per cent. of carbon both temperatures of liberation of heat are associated with change of magnetic condition.

OVERHEAD TROLLEY WIRES A GOOD THING.

President G. B. Roberts, of the Pennsylvania Railroad Co., has come out strongly for overhead wires for electric street railways. Speaking of the statement that the overhead wire system was dangerous President Roberts said:

"I don't believe as many horses are killed or hurt by overhead wires as on this asphalt pavement around the City Hall; but for that reason we would not replace that pavement. More people are killed in London by slipping on orange peels than by railway transportation accidents in all England. Really and seriously, all the dangers of overhead wires are so slight that they are overbalanced by the advantages, and we must take some risks in every enterprise. I have no interest, not a penny, in this system. I should grant every road overhead wires without reference to the dangers."

The Rapid Transit Commission has declared in favor of overhead wire roads west of the Schuylkill, north of Columbia avenue, and south of Washington avenue, Philadelphia.

1. Abstract of a paper read before the Royal Society.

NOTE ON THE LAW OF HYSTERESIS.

BY CHAS. STEINMETZ.

The magnetism of a magnetic circuit will vary periodically, if subjected to a periodically varying magnetomotive force. The variations of the magnetism, however, will not be simultaneous with the variations of the magnetomotive force, but show a certain lag, so that the curve of magnetism, as a function of the magnetomotive force, forms a kind of loop, the well known curve of hysteresis.

This phenomenon proves, that in the production of the magnetic circuit by the conversion of electric energy into magnetic energy, and in the destruction of the magnetic flow by its reversion into electric energy, a certain amount of energy has been lost, that is, converted into heat.

The amount of energy converted into heat by hysteresis in a full magnetic cycle depends on the maximum magnetization. It increases with increasing magnetization, but faster than the magnetization, so that, when for a magnetization of $\mathbf{B}=3{,}000$ (3,000 lines of magnetic force per square centimetre) the loss by hysteresis amounts to 736 absolute units or ergs per cubic centimetre (10^7 ergs=1 watt-second); for four times as high a magnetization, or $\mathbf{B}=12{,}000$, the loss is 6,720, that is, more than nine times as high. On the other hand, the loss increases more slowly than the square of the magnetization, because the square law would require a loss of 11,776 for $\mathbf{B}=12{,}000$.

A great number of experimental researches on the loss of energy due to hysteresis, with different magnetizations, have been made by Ewing; but that law of nature is still unknown, which gives the dependence of the hysteresis upon the magnetization.

In trying to find at least a clew to this law, I subjected a very complete set of Ewing's observations on the hysteretic energy, made on a soft iron wire, and consisting of ten tests from a magnetization of 1,974 lines of magnetic force per square centimetre, up to 15,560 lines per square centimetre, to an analytical treatment by the method of least squares, to ascertain whether the losses due to hysteresis are proportional at all to any power of the magnetization, and which power this is.

The results of this calculation seem to me interesting enough to publish, in so far as all those observations fit very closely the calculated curve, within the errors of observation, and the exponent of the power was so very nearly 1.6, that I can substitute 1.6 for it, and combine those observations of Ewing in the formula

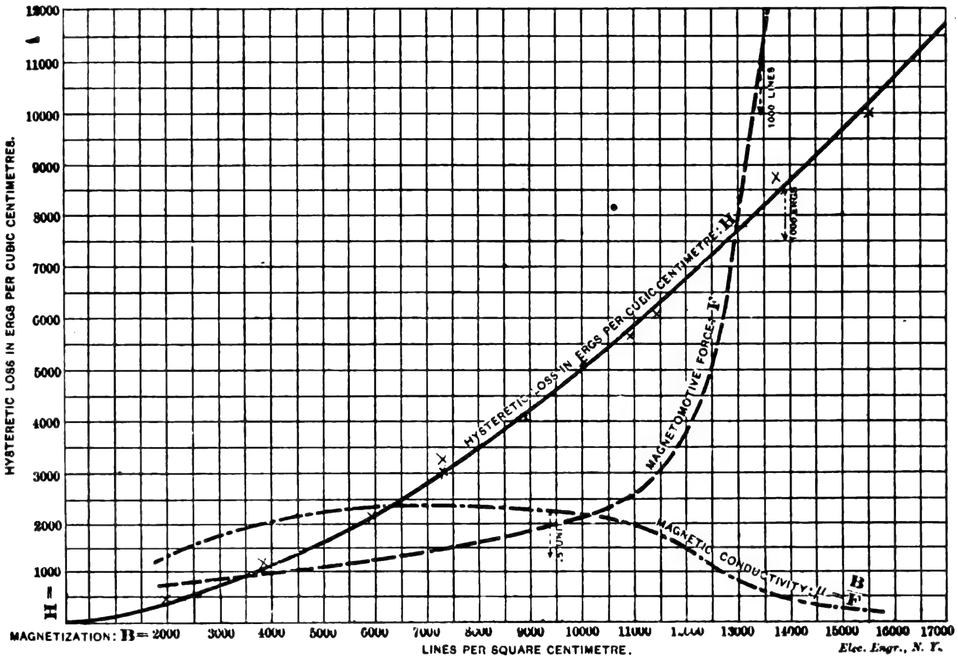
$$\mathbf{H}=.002\ \mathbf{B}^{1.6},$$

where $\mathbf{H}$ is the loss due to hysteresis, in ergs per cubic centimetre ($=10^{-7}$ watt-second) per cycle, and $\mathbf{B}$, the maximum magnetization (number of lines of magnetic force per square centimetre).

In Table I., in the first column, are given the values of the magnetomotive force $\mathbf{F}$, in absolute units; in the second column is given the maximum magnetization or induction, $\mathbf{B}$, in lines per square centimetre; in the third column the magnetic conductivity $\mu=\dfrac{\mathbf{B}}{\mathbf{F}}$; in the fourth column the hysteretic loss $\mathbf{E}$, in ergs per cubic centimetre, as observed by Ewing, but in the fifth column the hysteretic loss calculated by the formula:

$$\mathbf{H}=.002\ \mathbf{B}^{1.6}.$$

The sixth column gives the differences of the observed and the calculated values, $\mathbf{E}-\mathbf{H}$; the seventh column gives these differences in per cents. of $\mathbf{E}$.



Loss by Hysteresis at Different Degrees of Magnetization.

In the diagram these calculated values, $\mathbf{H}$, of hysteretic loss are shown in the curve; the black crosses show the values of hysteretic loss $\mathbf{E}$ observed by Ewing.

For comparison there are shown, in dotted lines, the curves of magnetomotive force $\mathbf{F}$ and of magnetic conductivity, $\mu=\dfrac{\mathbf{B}}{\mathbf{F}}$, as functions of the magnetization $\mathbf{B}$.

It will be seen that the observed values of hysteretic loss are very near the calculated curve through the whole range of observation, and do not show any tendency to deviation, which justifies my considering this coincidence as something more than a mere accident, and, indeed, as an indication of a general law, although certainly this law might be more complicated than the formula.

In Table II. are given the values of hysteretic loss, calculated by the formula:

$$\mathbf{H}=.002\ \mathbf{B}^{1.6}.$$

To one interesting fact I wish to draw attention: The hysteretic loss seems to be independent of the magnetomotive force $\mathbf{F}$, and only dependent upon the magnetiza-

tion **B**; it therefore shows no special singularity at the point of the beginning of magnetic saturation, but increases in the last two observations in Table I., which, for an increase of **B** by 3,500, require an increase of **F** by 68, showing high saturation, according to the same rule as in the first eight observations, where $\mathbf{B}=12{,}000$ corresponds to $\mathbf{F}=7$. Therefore the "knee" of the magnetic curve or "characteristic,"

$$\mathbf{B}=f\ (\mathbf{F}),$$

is no singular point of the curve of hysteresis $\mathbf{H}=.002\ \mathbf{B}^{1.6}$, as the diagram shows.

From this formula we get the loss due to hysteresis per cubic inch of soft iron and for the maximum magnetization of M lines of magnetic force per square inch, when n = the number of complete periods of the exciting alternate current:

$$\mathbf{H} = \tfrac{5}{8} \times 10^{-10}\ n\ M^{1.6} \text{ watts.}$$

TABLE I.

Comparison of Ewing's observed values of **E**, the energy consumed by hysteresis in soft iron, with the values calculated by the equation:

$$\mathbf{H}=.002\ \mathbf{B}^{1.6}.$$

THE EDISON GENERAL ELECTRIC CO.'S ELECTRIC PERCUSSION DRILL.

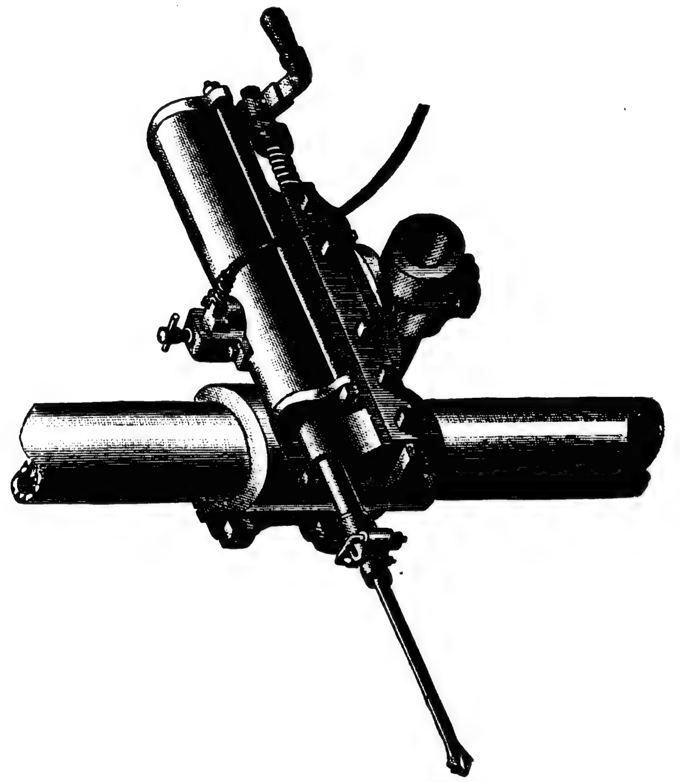
THE one thing which has more than anything else prevented the all but universal application of electric motive power to mining operations, has been the lack of an efficient and practical electrical substitute for power drills operated by steam or compressed air.

The Edison General Electric Company, appreciating this fact, have obtained control of and are now manufacturing and exploiting a drill making use of the principles of the "Marvin system of percussion tools." This drill, a cut of which is here shown, consists simply of a reciprocating iron bar impelled backward and forward by the action of two solenoids which are alternately thrown into action by pulsating electric currents.

This alternate action of the two coils is accomplished without the aid of commutators, collectors or other moving parts on the drills which are involved in reciprocating motions in other machines, but is accomplished by the use of pulsating currents, positive impulses being delivered to one coil and alternately negative impulses to the other. Since there are no moving parts in the drill except the reciprocating bar or plunger, there is no wear except in the guides. The heaviest parts of the drill are the tripod weights which weigh about 100 pounds each, and the two solenoid coils which weigh 55 pounds each; and the largest piece is the cylindrical casing in which are enlosed the coils, which is 38 inches long by about 6 inches in diameter. The total weight of drill and tripod is about 400 pounds.

The drill makes about 600 strokes per minute of a maximum length of about 4 inches and will cut at the rate of two inches per minute in the hardest granite with a one and one-half inch bit, with a consumption of about 5 h. p.

One of the most remarkable features of this drill is that



MARVIN ELECTRIC DRILL.

should the machine not be fed up to the rock properly, so that the bit fails to strike, the plunger immediately loses its stroke and its motion drops to a mere quivering action of about one inch travel. The plunger is automatically cushioned by the magnetic action of the coils and vibrates in space without striking anything at either end of the stroke. The machine cannot therefore injure itself while thus running free.

It may also be forced hard against the rock so that it cannot take its stroke, and left in this situation with the current on indefinitely without injury and with little waste of energy, as the power absorbed by the drill is automatically proportioned to the work it does. It is practically impossible to run the machine in such a way as to injure it.

The drills are run in parallel. The current, which is pulsating, is derived from a generator exactly similar to the standard Edison dynamo, except that it is supplied with pulsating current collectors, in addition to the regular commutator. The machine is thus self exciting and allows of continuous current apparatus being run on a separate circuit from it, at the same time that pulsating currents are delivered to the three wires leading to the drills.

HOW TO MAKE GREAT ELECTRICAL INVENTIONS.[1]

BY EDWARD P. THOMPSON.

The author of the paper discussed at the outset the methods by which a would-be inventor should address himself to his work. Any given individual, he said, takes a step toward becoming or improving himself as an inventor who studies the need of the public; learns the difficulties connected with that department of art or industry in which the need exists; excites his mind with the belief that he can provide means to remove the difficulties; and proceeds with diligence toward the solution of the problem.

The truth of this problem is strengthened by its negative aspects. Suppose the first step should be, *not* to study the need of the public. The consequence would follow in many cases, in the production of useless inventions; *i.e.*, those which accomplished results not wanted. This often does occur. As an illustration may be mentioned, parlor skates. An inventor of an improved parlor skate for to-day is an inventor of that which has no market, as skating rinks have gone out of fashion and lost their popularity. It is something which the public does not want, even though they did pay a tribute of many thousand dollars to the first inventor of the parlor skate.

The second element of the principle before stated consists in learning the difficulties connected with that department of art or industry in which the need exists. If there is any one difficulty in connection with any department of art, the would-be inventor may be sure of reward if he succeeds in overcoming the difficulty. How is he to become aware of the difficulty. He is to make a business or study to this end. If he is engaged with a manufacturer he can daily become acquainted with difficulties which prevent the manufacturer from clearing as much profit as he should. If he is a student or scholar of science he can become acquainted with difficulties by studying any particular art. If he is a business man, he can learn difficulties by the habit of observation of difficulties met with by himself. In connection with his own business, any man can in the course of at least a week learn some difficulty if he will only keep his wits about him and be on the lookout. He may meet it in traveling, in business, in his home, in his conversation with others, in the newspapers and in other directions. At the present moment exist problems well known to many, but yet unsolved, and of all degrees of magnitude and in all departments of every art.

Mr. Thompson here instanced such promising fields of work as alternating current motors, electrical storage, conversion of electricity into heat and *vice versa*, the storage of light, new light giving media, transmission in fac-simile; mail transportation by electricity; new electrical generators, electrical watches, electric meters, commutatorless dynamos, cheap aluminum.

Discussing the hindrances to the progress of invention, Mr. Thomson said: Some are desirous of being inventors. They know they have a taste that way. They admit that there is room for improvement and for original invention. They have studied the principles of science or of a particular art. They believe that others may and will invent. Ask them why they do not invent. The invariable reply is that they believe they possess no genius or inventive faculty. They imply that some have been born and gifted with what they have not. This is not true. Every man has more or less power of inventing. Every day every one busily occupied, uses his power of faculty of inventing, when he plans, in imagination, his business of the day, or whenever he thinks of the best way of carrying out an idea. Let one once believe that he does possess the power to invent and it will not be long before he will know that the field of invention is shut against none. A friend once told me he could never invent any new and useful device, because he believed that he had no genius. I undertook to prove that genius was a latent power in all and could be brought out by a voluntary action on the part of the mind, and that the creation of a conception depended vastly more upon systematic thought, knowledge, and a determination to invent than upon the vague myth called genius. Within one month thereafter, the same person came to me with a complete conception which became a successful physical invention, original in a patent sense and highly commercially valuable and practical. From observations of a similar nature I conclude that the following principle is true: A belief of an individual that he himself does not possess genius or the power to invent, is in itself a hindrance to the action of that power.

The corrollary which follows is: An individual who will admit that he possesses a power of inventing to a greater or less extent may become an inventor by the proper use of his knowledge. Suppose that the inventor of the device for threading needles insisted previously upon the assumption that he had no genius. He did not so assume. Consequently he received an annual income of $10,000 from the sales of his patented needle threader, which was at one time so popular a device. The inventor of the roller skate cleared nearly $1,000,000, although during only the last few years of the term of the patent. Neither did he make the invention until after many days of intense thought.

Will any civilized white man assume he has no inventive faculty or genius when it is a fact that the patent office records show that colored men are inventors. I am personally acquainted with a colored man who has not only made electrical inventions and received letters patent of the United States, but has sold the same. His extreme confidence in his ability to invent, is easily apparent to those who know him. Some of his inventions are now in use and show a high type of invention; therefore it seems but proper that due honor should be given by mentioning his name. I refer to Granville T. Woods, of Cincinnati, Ohio.

With regard to the difference in the nature and scope of inventions, Mr. Thompson said:—

A radically new invention is properly called a generic invention because it prefaces successive specific or derived inventions. As an example of a generic invention may be mentioned the method of transmitting speech electrically. Since 1876, the date of that invention, numerous specific inventions have been made, patented and put into practical use with profit to the inventor. As an example of a specific invention, may be mentioned the Edison-Blake transmitter, without which telephony may easily have become extinct. This transmitter magnifies the sound so that users are not troubled by inaccurately transmitted speech as before the introduction of the wonderful but simple carbon transmitter. As another illustration of generic and specific invention may be named the original phonograph, while all subsequent improvements, modifications, mostly made by the original inventor himself, are specific inventions.

The first steam engine is a generic invention, while all later are specific. The first chemical battery is a generic invention. All others are specific. The first dynamo is generic; subsequent dynomos are specific. The first telegraphic message was sent by a generic invention. Subsequent improvements, modifications, etc., are specific.

From investigation of the inventions of the two classes, it is discovered that all generic inventions are made by the application of purely scientific principles and specific inventions sometimes in the same manner, but oftener by the application of the principles of mechanics than by those of pure science.

As an illustration of the production of a generic invention take the case of the arc lamp. Before its invention, the principle was known that momentary light is produced by interrupting an electric current. The inventor effected an artificial permanent light by applying this principle. By experiment he found that the light or spark gradually consumed the electrodes. He provided means for forcing together the electrodes as fast as they were consumed, and he thus produced one of the most useful inventions of to-day.

The following principle of the science of invention holds true in reference to all past generic inventions and it may, therefore, be assumed to hold true for all future generic inventions. It is formulated thus:—A generic invention may be made by combining one or more principles of physical, electrical, or chemical sciences to a new and useful purpose. The corrollary to this is:—Any given problem of generic invention may be solved by becoming acquainted with the principles of physics, electricity and chemistry, and then searching for principles which by their combination will produce the result sought.

Both of these principles prove the preference and almost the necessity of thorough scientific education on the part of the inventor. I believe it would be for the good of the industrial arts and the public to establish in our various scientific colleges, a class for the development of the power of inventing. At present, students study science and store it away in their brains as though the storage was to be permanent. By the time they undertake to use the knowledge, they have forgotten most of it.

Mr. Thompson advised his hearers not to be discomfited by "anticipations," which should only be an incentive to further effort. At the same time he cautioned against working on evidently played-out lines. "I do not intimate," he said, "that any one here is undertaking impossibilities, but they may be wasting time in a path in which others for scores of years have failed. I mention as an example thermo-electricity by contact of different metals. Give it up! but if you wish to work on this subject in general, try the solution of conversion of heat into electricity in some other line than by the contact of different metals. Clamond spent thirty-five years on this subject with scarcely any improvement over his predecessors."

With regard to simultaneity of invention, Mr. Thompson remarked that inventors could not be too careful and quick in having their inventions properly described and attested "even if they do not apply for a patent immediately. The drawings and descriptions of the first mental inventions should be signed, witnessed and executed before a notary public if possible, on the day of conception." But, he added: "Do not trust to accident nor to inspiration nor to any mythical spirit or genius to make your invention for you. Do not expect the invention to come to you without any exertion on your part. For thirty years, the electric motor was known, but was not operated by power to obtain a current. For thirty years the red lead and litharge occurred on the lead plates after discharge. Obtaining with a view to invention an accurate knowledge of the scientific nature of the elec-

1. Abstract of a paper read before the New York Electrical Society, December 10, 1890.

tric motor and of the early secondary battery was the factor which made the respective inventions." Moreover, "as soon as any one, either by investigation, alone or with the assistance of a chemist or physicist, or as soon as a scientist or any individual announces a scientific fact or principle not known before, embrace the opportunity of being the first to apply the fact or principle to a useful purpose. In reading periodicals or scientific papers have this rule of invention in view. Look out for the results of scientific investigation, not as a student who simply reads as a matter of obtaining knowledge, nor as a critic, nor as a pastime, but for the single and concentrated purpose of being the pioneer in the application. As soon as Faure made his invention there were scores of immediate and independent inventors, who conceived the improvement of compressing the active material into small cells or perforations in the lead plate for the two-fold advantage of obtaining more metallic surface, and of retaining the active material in its proper place, since if applied to a flat lead surface, it is apt to fall off gradually but surely. I have found that the least number who made this invention and are continuing to make it may be estimated at about one hundred and twenty-five. Some one was of course the first, but it makes no difference here who it was, but as I remember, the United States Courts have decided n favor of Charles F. Brush. The question is sometimes asked by the thoughtless, of what use is it to spend a fee to belong to an electrical society or to be a subscriber to a scientific paper, or to study the numerous patents granted? The man who wishes to be a successful inventor, cannot afford to despise such things.

"The history of the invention of the carbon transmitter strengthens this principle of invention. In 1878 Edison discovered the scientific principle that all semi-conductors have the property of varying the current according to the pressure. Four years later, when inventing in the subjects of telephones he recalled the new knowledge and by introducing semi-conductors into a circuit and talking against them he thereby applied the new knowledge to a useful purpose."

On the subject of "Simplicity as the Result of Specific Invention," Mr. Thompson said:

"It is a remarkable principle that the final type is simpler in construction than the generic invention and that simplicity detracts from originality. The first telephone transmitter was more cumbersome and costly than the present; while the first envelope machine was as confusing in appearance as the wisps of hay in a hay stack. Many men wonder why they could not have invented the telephone. They should be reminded of two things; they either did not try or else they think that the first unsuccessful telephone was as simple as the present. Bell's earliest telephone was for transmitting music and its construction was as intricate as a piano or typewriter. Nearly every generic physical invention is of low efficiency, complex and intricate in construction and tending very much to drive the inventor into despair. If he has evidence that he is on the right track he should not stop for such difficulties by abandoning the invention and finding afterwards that others commenced where he left off and brought out a successful commercial article. It is far better as a last resort to get the assistance of another inventor at the expense of a portion of the interest in the patent and act thereby in accordance with the old proverb that two heads are better than one."

The important question of experimenting was not forgotton. "Different inventors," said Mr. Thompson, "follow different paths in the process of inventing. In some cases they perform experiment upon their conceptions. One experiment leads, in their mind, to another with new suggestions, until finally they are able to decide upon the fact of the invention as to whether it is operative or not. This is the most economical method. It in itself trains the mind to the power of intense imagination and power of invention. Many preliminary experiments may often be dropped by studying books on the subject to discover just what facts and principles exist that bear on the subject in hand. Many inventions have been made successful upon completion of the first device. A pencil and piece of paper will greatly aid the imagination and will save much useless experimenting. This method of inventing is followed mostly by highly scientifically educated persons, such as professors of the sciences at colleges. I lately visited at his home an inventor of a 'Put a Nickel in the Slot and Have Your Photograph Taken.' The machine did all the work. It was automatic from the beginning to the end of the process. Although mavellous to behold and apparently intricate, it was the result of the very first experiment, and it did its work not only well, but every time. I found that it took but two months for him to reduce the mental invention to the physical; but to devise the complete mental invention, and to experiment with all the movements in the mind, assisted by pencil and paper, occupied the larger portion of a year.

"Some begin to experiment upon the very first conception, and even build a full sized machine or apparatus at the first, and when the difficulties are found, another machine is built, and so on. This method is more expensive and requires more time, and does not in itself increase the power of imagination, which is one of the greatest aids to an inventor. A harmonious blending of these two methods makes the greatest inventor.

"The style followed by the chemist and physicist in their experimenting for new principles, is often copied by successful inventors. The former use small and almost minute quantities and apparatus costing very little. Small experiments are positive and often more so than large experiments. Planté experimented upon his secondary battery with small quantities of chemicals costing but a few cents each. Distribute your time and money on numerous small experiments rather than upon a few large ones.

"Experimenting for the purpose of solving a certain problem often leads to the solution of an independent and unexpected problem. Glauber searched long and diligently for the philosopher's stone, and by putting certain chemicals together for this purpose found that he obtained a substance radically different from either of the constituents. The compound thus produced is the medicine which bears his name."

THE PRESENT STATUS OF STORAGE BATTERY TRACTION.[1]

BY PEDRO G. SALOM.

Just at a time when so much interest is being manifested by the public in relation to the discussions before councils on rapid transit and electric traction, it is pertinent and but simple justice to the public that they should know the exact status of storage battery traction.

This much abused system, which has never yet had a fair and untrammelled trial in this country, but which, nevertheless, is bound to supersede in the near future all other systems of electric traction in large cities (whether overhead or conduit), asks to be heard on the following grounds:

First. It is admitted that a storage battery car will run well even under unfavorable and difficult conditions.

Second. That the mechanical construction from the motor to the wheels is practically the same (and can be made, if desired, exactly the same) as the now generally admitted successful overhead system.

Third. This being the case, if it can be shown that a certain weight of battery, at a given price, can propel a car a given num- of miles, and that the cost for battery in doing this work does not exceed a certain maximum fixed price, which, together with the other operating expenses, is less than the cost per car mile with horses, then it must be evident to the dullest comprehension that there is a field for storage battery traction.

The question is entirely one of horse-power. Either a certain weight of battery will return a certain number of horse-power hours as effective work after being charged or it will not. The proposition in paragraph 3 is either true or false and is capable of verification by any well qualified electrical or mechanical engineer. The gentlemen engaged in the development of storage batteries are neither fools nor charlatans, and the company which I have the honor to represent court the most rigid and exhaustive investigation as to the truth of their statements.

If, for example, a commission composed of such men as Mr. Coleman Sellers, Professor Rowland, Dr. Dudley, and Professor Barker pronounce on this question as to the ability of the battery to perform such work for such a price, it must forever remove the question of uncertainty and doubt hanging over the system at the present time.

We are now prepared to prove, and to guarantee under proper conditions, that the cost per car mile for renewals shall not exceed a certain maximum rate per mile based on the amount of work required for any given installation.

The fact that certain individual installations of two or three cars have failed to be commercial successes proves nothing, except, perhaps, that they are badly designed to accomplish the work required. No one would condemn a locomotive for failure to run from New York to Chicago without receiving additional fuel and water above that of the initial charge. Therefore, if in a certain case a car fails to run, say, twelve miles on time, assuming that the mechanical equipment is right, it shows either that the type of accumulator used is too small, or, that there is an insufficient number of them to do the work, both of which are mechanical errors that can be easily overcome in designing new cars in the future.

The overhead system, by reason of its simplicity, received the generous support of capitalists, notwithstanding the fact that all the early installations were absolutely commercial failures, and even Siemens & Halske, probably the foremost and oldest established electrical engineers in the world, were so discouraged by their numerous and expensive efforts to make electric traction other than the storage system a success, that they abandoned all hope of ever doing so until the recent achievements of American engineers in that direction revived their early expectations.

Moreover, even if the overhead system gains a temporary advantage by being introduced at the present time, the street railway company will be forced by the inevitable logic of events to adopt the storage system in the future. Those who are clamoring loudest for overhead traction to-day will ultimately be the most earnest advocates of storage battery traction.

1. Letter to *Philadelphia Telegram* from the Secretary of the Consolidated Electric Storage Co.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

THE TANNING OF SHEEPSKIN.

[151.] We read with great interest your article on "Tanning by Electricity," in your issue Nov. 26th, and would put a few questions to you which probably can be solved by one of your correspondents. We are tanning sheep, lamb, goat and calfskins into kid leather with alum and salt. It requires only a few hours to tan the skins, so electricity wouldn't help us any as far as time is concerned, but sheep and lambskins contain a great deal of fat, which at present we extract after the skins are tanned, by putting them into naphtha over night. Now we would like to hear whether it wouldn't be possible to extract this grease with electricity during the tanning process. If any of your correspondents wish to try the experiment we shall be glad to furnish them with the skins, or if they want to try it at our factory we shall be glad to furnish them with anything they need. If this can be done without too heavy expense, the one who invents the system will be able to make a fortune. WINTER & GOETZ.

READING, PA., Dec. 9, 1890.

EUROPEAN CORRESPONDENCE.

LONDON.

Dinner of Electrical Engineers.—Central London Railway.—Overhead Wires Bill.—Lineff System.—Northfleet Electric Trains.—Montevidean Telegraph Company.—Expiring of Telephone Patents.

LAST Thursday evening the second annual dinner of the Institution of Electrical Engineers was held at the Criterion Restaurant. Dr. Hopkinson, the president, occupied the chair. There was a goodly muster of men connected in various ways with electricity, who sat down to a repast well served up by Spiers and Ponds. Among those present were: Mr. Raikes, the Postmaster-General, Sir Richard Webster, the Attorney-General, and Dr. Coleman Sellers, of America. On the whole it was not considered a lively evening. Speeches were in the main dull and tedious, the wit being entirely in the hands of the Attorney-General and the Toastmaster. Mr. Raikes, in returning thanks for Her Majesty's Ministers, said that the department over which he presided had closer relations with electricity than any other department of the State. It was an interesting fact that during the nineteen years of Governmental administration of the Post Office the number of telegrams had grown from 10,000,000 in 1871 to 62,500,000 in 1889. He recalled with pride that the Post Office had given no less than three presidents to the Institution, Mr. Scudamore, Mr. Preece and Mr. Graves. It was not in this department alone, however, that electricity entered into the service of the Government. The Board of Trade had special and important relations in the working of the Electric Lighting Acts. Many who were there that night thought electric lighting had been unduly arrested by the jealousy of Parliament. He understood the feeling, but did not share it. When a new science appeared it was desirable that time should be given for it to develop. The authorities had been wise in holding their hands for some years before taking any decisive steps in licensing and extending the use of electric light. The speaker then went into the subject of electricity in the Navy.

Sir George Stokes responding on behalf of the "Learned Societies" referred to his probable successor as president of the Royal Society, who without much doubt would be Sir William Thomson. Mr. Raikes in proposing the Institution mentioned that the number of members in 1872 was 268, at the present time it was 1,738, an increase of 1,470. There were two students in 1872, now they had over 102.

I hear that it is probable that the Central London Railway will apply again to Parliament for the necessary powers to erect an underground railway worked by electricity. It will extend from Bayswater to the city, along the line of Holborn and Oxford street. Last session the bill was thrown out in the House of Lords on the ground that there was no successful operation of a like nature to point to. If then, the South London Railway proves ultimately to work well, there appears to be no valid reason for preventing a similar undertaking in another part of London.

The London County Council propose to bring in an Act to Parliament which will enable them to control the whole of the overhead wires in London.

The Lineff system (closed conduits) of electric traction will now have opportunities of proving its practicability on a length of line of 8½ miles. The Hammersmith Vestry last week granted full permission.

As the object for which conduit cars were run on the Northfleet road has been accomplished, the electric trams have ceased to run, and we may expect shortly the report of the working during the past eighteen months.

The Montevidean Telegraph Company at an extraordinary meeting held yesterday, passed resolutions to wind up the concern and to transfer the whole business to the Western and Brazilian Company, under an arrangement favorable to the shareholders.

As the time draws near for the expiring of the telephone patents owned by the National Telephone Company, the struggle becomes very keen where other companies work by license a telephone business. For the past eleven years a highly successful telephone exchange, conducted by a local company, has been in existence in Sheffield, and during the latter portion of that period the National Company has also had an exchange in the same town. As the expiration of the telephone patents approaches, the competition between these companies grows keener, and the rates now charged in Sheffield will probably become general throughout the country. The town company recently announced a reduction of rates to £7 per annum, and this was at once followed by a reduction on the part of the National Company to £5 per annum. In view of the arrangements that are being made to challenge the monopoly of the National in all large centres by properly constituted companies, it remains to be seen how soon this company will realize the nature of the coming struggle, and how soon it will meet the same by a general reduction of rates to the level arrived at in Sheffield. Meanwhile the Sheffield Company is preparing to join hands with the new companies for mutual support, and if inter-town communication is to be a real necessity of future telephonic developments it may reasonably be anticipated that through wires for the same will be readily provided by the Postmaster-General and probably on terms less burdensome than those of the National Telephone Company. H. S.

LONDON, Nov. 26, 1890.

CORRESPONDENCE.

CHICAGO.

Extending the City Circuits.—The Bear Magneto Electric Co. Formed.—An Electric Car Train-Struck.—Adoption of Electric Welding-Calumet Electric Railway.

ELECTRIC lights have now been placed on Lake street from Ashland avenue to Western avenue. They are operated from the city power house at Troop and Van Buren streets, which is intended to supply the whole of the West Side. It is not decided whether any more lights will be put in this winter, but eventually the street will be lighted all the way down town.

The Bear Magneto Electric Co. has been incorporated, with a capital stock of $3,000,000, to do a general light, heat and power business. The double armature dynamo which the company proposes to use is the invention of Mr. J. M. Bear, one of the incorporators. The machine is to be made portable so that it can be set up wherever light is required. The incorporators of the new company are S. J. M. Bear, William R. Northway and Franklin Babcock.

An electric street car at a railroad crossing in Wichita, Kan., was struck by a train running twenty miles an hour, knocked forty feet and almost completely demolished. The motor man jumped and escaped with slight injuries. There were only two passengers in the car at the time of the accident. They are thought to be fatally injured.

The manufacturing firm of Craver, Steele & Austin, located at Harvey, Ill., are about to introduce the process of electric welding into their works at that place. With this process, as is now well known, with suitable apparatus, it is possible not only to weld iron and steel, but also metal which heretofore could not be successfully united. Pieces of such metals and alloys as wrought iron, copper, silver, brass, lead, tin, aluminum and even cast iron, can be not only melted to each other, but the different metals can be welded together. The tensile strength of the weld as demonstrated by mechanical tests, has proved to be highly satisfactory.

Two Calumet electric street railway ordinances were presented by Alderman Gorman, at the council meeting last week, one being the complement of the other. The routes indicated are 1. Beginning at the intersection of Seventy-ninth street and Cottage Grove avenue, thence south on Cottage Grove avenue to 87th street, also commencing at the intersection of 93d street and Cottage Grove avenue to 95th street.

2. Beginning at the intersection of Cottage Grove avenue and 93d street, thence west on 93d street, extended to South Park avenue, extended thence south on South Park avenue, extended to 95th street, thence west on 95th street to Stewart avenue. The fare is to be five cents and the road is to be in operation within a year after the passage of the ordinance.

CHICAGO, Dec. 12th, 1890.

SOCIETY AND CLUB NOTES.

PROVIDENCE MEETING OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

The following notice has been issued by General C. H. Barney, chairman of the committee on exhibits:

In connection with the meeting of the National Electric Light Association in Providence, R. I., on February 17th, 18th and 19th, 1891, it is proposed to hold an exhibition of electrical apparatus and appliances, especially such as are used in the business of furnishing light and power. To this exhibition, all Associate members are earnestly requested to contribute.

A suitable hall has been secured opposite the hotel which will be the Association headquarters, and through the courtesy of the Narragansett Electric Lighting Co., all the electric current necessary will be provided. There will be run into the hall, three circuits, viz: 1st, an incandescent alternating current converted to 50 volts; 2nd, a 500 volt direct current from T.-H. generators; 3d, an arc current of $6\frac{8}{10}$ amperes.

There will be no charge for space or current to exhibitors, who must, however, be Associate members of the Association. The installation and care of exhibits will of course be at the expense of exhibitors.

As this meeting may be said to virtually mark the close of the first decade of electric lighting, commercially, it is suggested that as far as possible, efforts be made to show the progress in the art, by exhibiting the earlier forms of apparatus and appliances, together with those embodying the latest improvements.

The exhibition will open on Tuesday, February 17th, and close on Thursday evening, Feb. 19, and will be open day and evening. Exhibits may be installed on the Saturday and Monday previous, and removed on the following Friday.

It is expected that this exhibition will prove very attractive to the Providence public, as well as to the members of the Association. To exclude the street gamin element, a nominal admission fee (25cts.) will be charged, but it is intended to circulate complimentary invitations freely among the representative business men of the city, and exhibitors will be supplied with as many complimentary tickets as they may desire to distribute.

As space is limited and will be allotted in the order in which applications are received, it is desirable that all intending exhibitors apply to the Chairman of the Committee prior to January 15th 1891, at which date all allotments of space will be made.

BOSTON ELECTRIC CLUB.

The annual meeting of the Boston Electric Club was held at the club rooms this week, writes our New England representative, President Cram presiding, at which there was a good attendance. The following officers were unanimously elected: President, Capt. Eugene Griffin; vice-presidents, C. J. H. Woodbury and C. L. Edgar; treasurer, F. J. Boynton; secretary, R. F. Ross; historian, G. W. Mansfield; directors, *for one year:* J. Edward Addicks; George E. Hanson; John C. Wilson; Wm. Brophy; Chas. B. Burleigh. *For two years:* A. L. Rohrer; Henry B. Cram; R. F. Ross; L. S. Dumoulin; George B. Neal. *For three years:* F. J. Boynton; Frank H. Monks; George W. Adams; Wm. C. Woodward; W. J. Denver. *For four years:* Frank Ridlon; E. H. Hewins; J. R. Lovejoy; W. D. Warner; C. W. Holtzer.

At the close of the meeting Captain Brophy, in a few well-chosen remarks, presented, in the name of the club, to President Cram an excellent picture of himself. Mr. Cram in thanking the members, took occasion to say that he was of opinion that the club was now in a more successful condition than ever, and that he looked forward to the coming winter with every degree of hopefulness for its continued prosperity. A few happy speeches were made by a number of the members, and the house and entertainment committee stated that they had a number of entertaiments and lectures in preparation.

PROF. CROCKER TO LECTURE BEFORE THE NEW YORK ELECTRIC CLUB.

The regular monthly meeting of The Electric Club will be held Thursday evening, December 18. Prof. Francis B. Crocker, of Columbia College, will lecture on "Electrical Units of the Present and Future." Prof. Crocker will review the derivation of, and relations between, the present electrical units, and discuss the creation of other electrical units which now are, or soon will be, required in electrical science and industry. It is proposed to treat this subject, as far as possible, in a non-mathematical manner, and give the most important facts regarding electrical units in popular yet comprehensive language.

A brief business meeting of the club will be held at 8 o'clock to discuss proposed amendments to the by-laws. The lecture will begin promptly at 8:30. This is the last meeting of the present year, and every member should attend. The club's regular dinner (costing $1) will be served from 6 to 8 p.m. Members who expect to dine at the club should notify the clerk at the Club House.

REPORTS OF COMPANIES.

COMMERCIAL CABLE CO.

Two men who have a right to be happy just now, says the *Morning Journal* of Dec. 7, are John W. Mackay and Manager George G. Ward, of the Commercial Cable Company. Amid all the Wall street stringency the company's shares held firm as a rock, and with good reason. Its latest declared dividend of 1¾ per cent. shows that it has become a 7 per cent. stock—a triumph for pluck, good service and good management.

EDISON ELECTRIC ILLUMINATING COMPANY OF NEW YORK.

The Board of Directors of the Edison Electric Illuminating Company of New York have declared a quarterly dividend of 1 per cent., payable January 15, 1891. In addition, the directors have declared a dividend of 5 per cent. on its capital stock, representing surplus earnings, payable in certificates convertible into stock at par whenever the company shall increase its capital stock beyond the present authorized amount, or redeemable in cash, at par, at the option of the company. Until so converted or redeemed these certificates will bear interest at the same rate, and payable at the same time, and in the same manner, as dividends may be paid on the company's capital hereafter. These dividends will accrue to stockholders of record January 2. Convertible certificates will be delivered on and after February 2. Transfer books reopen January 21.

WESTERN UNION TELEGRAPH COMPANY.

The Board of Directors have declared a quarterly dividend of one and one-quarter per cent. upon the capital stock from the net earnings of the three months ending December 31st instant, payable at the office of the Treasurer on and after the 15th day of January next to stockholders of record at the close of the transfer books on the 20th day of December inst.

THE AFFAIRS OF THE WESTINGHOUSE CO.

A special dispatch from Pittsburgh of Dec. 10 says: "The committee of local bankers recently appointed to investigate the financial standing of the Westinghouse Electric Company finished its labors to-day. Its report is understood to be favorable. The committee determined that the electric company stocks are worth over $25 per share, and decided to advance the $500,000 recently requested by Mr. Westinghouse, on condition that the parties making the loan have the privilege of naming the general manager for the company. The full Board of Managers of the Westinghouse Electric Company, at its meeting this morning, resolved to request the stockholders, at their meeting this afternoon, to issue $3,000,000 of preferred stock." This is to be done.

DIVIDENDS.

THE EASTERN ELECTRIC CABLE CO. has declared its regular semi-annual dividend of 3 per cent. on its preferred stock, payable Dec. 16, 1890.

DULUTH, MINN.—The Duluth *Tribune* of Dec. 2 says: "The Hartman Electric Company, of which Alexander W. Hartman is president, held its regular annual meeting yesterday. The principal business consisted in the pleasant duty of distributing $8,000 among its shareholders. This amount constitutes the semi-annual dividend, and would appear to indicate a very successful company."

STOCKS AND BONDS.

QUEBEC, CAN.—A premium of 15 per cent. has been offered for some new shares of stock in the Quebec & Levis Electric Light Co., lately placed on the local market.

HUNTINGTON, IND.—The electric light and artificial gas plant, owned by Deck and Parker, has been sold to J. B. Townsend, of Lima, O., representing the "Brice syndicate."

SHEBOYGAN, WIS.—The German Bank has assumed control of the Sheboygan Electric Light Company's plant, and has also taken up the mortgage of $25,000 given by President Clarke for the money of which he claims to have been robbed in Milwaukee some days ago.

ALPENA, MICH.—The capital stock of the Alpena Electric Light Company has been increased to $84,000. The increase was on account of the large extension that is to be made to the works. Among the improvements will be an incandescent light system.

BRIDGEPORT, CONN.—The earnings of the Bridgeport Horse Railroad Co. were $84,000 last year; with the road and its extensions equipped electrically, it is calculated by Mr. J. N. Beckley that the earnings will be $200,000 the first year.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DEC. 9, 1890.

Alarms and Signals :—

Electrical Signal for Engines, M. Conley, 442,104. Filed Oct. 3, 1889.

Electric signal from the engine to the pilot or captain of a steamer, to indicate in which direction the shaft is revolving. Electrical contact-points are mounted upon the engine and made and broken directly by a movable part of the engine.

Non-Interference Fire-Alarm Signal-Box, P. V. Merrifield, 442,383. Filed March 7, 1890.

The non-interference mechanism in all the boxes in a circuit operate simultaneously so that "breaking in" is impossible until the alarm rung by the first pull is completed.

Electric Leak or Flow Detector, G. S. Neu, 442,385. Filed March 20, 1890.

First claim follows :

The combination, with a fluid-conduit having a valve-port, of a flow-detecting valve working perpendicularly to said port and provided with a stem also guided perpendicularly to said port, a circuit-closer, and a circuit-closer-operating rod coupled to the valve stem and working in alignment therewith, substantially as described.

Electric Bell, C. B. Beers and W. B. Tuttle, 442,473. Filed Nov. 16, 1889.

A bell and a "buzzer" combined in a single apparatus for producing two separate and distinct signals.

Conductors, Conduits and Insulators :—

Underground Electric Conduit, H. H. Young, 442,162. Filed June 23, 1890.

Consists of an outer conduit in jointed sections, an inner conduit of similar structure breaking joints with the outer conduit, packing interposed between two suspending plates within the inner conduit for the conductors, insulating material surrounding each, and a compound surrounding all the conductors; lids upon the sections of the conduits grooved to receive the upper edges of the body of the conduit. The body of the conduit is U-shaped.

Electric Connector, W. H. Garland, 442,370. Filed Sept. 19, 1890.

A device for connecting a small conductor to a larger conductor, as for example, a connecting wire to a railway track.

Consists of a cylindrical pin or plug with a straight, longitudinal groove on one side, of sufficient size to permit the connector to be placed upon the wire which it is desired to insert in the larger conductor, the edges of the groove being so arranged as to be compressed over the connecting wire when the connector is driven into a hole bored for the purpose in the rail or other larger conductor.

Conductor for House Lighting, W. H. Eckert and W. H. Gregory, 442,575. Filed Sept. 15, 1890.

The conductor is made in sections, each section consisting of an insulating tube having end plugs, a centrally arranged wire much smaller than the bore of the tube arranged therein, metallic heads in the end plugs to which the central wire is connected, the plugs being provided with screws for joining or separating the sections.

Dynamos and Motors :—

Electric Motor or Dynamo-Electric Machine, C. E. Dressler, 442,178. Filed April 14, 1890.

First claim follows :

In an electric motor or dynamo machine, a field magnet within the same composed of cylindrical sectors of like polarity connected to sectors of opposite polarity by cores wound with exciting coils of insulated wire within a zone separating said sectors, substantially as and for the purposes set forth.

Speed Regulator for Electric Motors, W. W. Schiffmann, 442,208. Filed April 28, 1890.

A series of graduated contact plates are embedded in the hand piece of a dental engine, and are electrically connected with a rheostat, for the manual regulation of the motor while the dental engine is in use.

Electric Motor and Frame, A. Schmid, 442,459. Filed Aug. 1, 1890.

Design and construction intended to cheapen manufacture and to secure greater durability and more convenience in handling and repairing, also to reduce the number of parts. Applicable particularly to motors for railway work.

Galvanic and Thermo-Electric Batteries :—

Carbon Electrode and Method of Making the Same, I. L. Roberts, 442,336. Filed Feb. 14, 1890.

First claim follows :

The method or process of manufacturing carbon electrodes, which consists in mixing together powdered carbon and an insulating binding material, such as paraffine or its equivalent, heating the mixture to fuse the insulating material, then subjecting the mixture to pressure in a mold to express the excess of insulating material, and then cooling it.

Galvanic Battery, C. E. Dutton, Jr., 442,516. Filed Sept. 6, 1890.

Design and construction of cell and elements with a view to securing the fixity of the parts in position and to secure portability without detriment to the cells.

Electrolysis :—

Separating-Diaphragm for Electrolytic Cells, I. L. Roberts, 442,203. Filed March 14, 1889.

The inventor discriminates between the "purely electrical resistance," and the "electrolytic resistance" of a separating diaphragm.

Claims 1 and 6 follow :

1. In an electrolytic cell, the combination, with the electrodes of an intermediate partition or diaphragm having a relatively high electrolytic resistance, as set forth.

6. A composite diaphragm or partition for electrolytic cells, composed of a gelatinous or equivalent substance, held by rigid or equivalent supports in the form of a dividing wall or partition between the electrodes, as set forth.

Diaphragm for Electrolytic Cells, I. L. Roberts, 442,204. Filed March 14, 1889.

Employs asbestos freed from soluble constituents as material for diaphragms.

Electrolytic Apparatus, I. L. Roberts, 442,332. Filed July 13, 1888.

Inventor employs in an electrolytic cell, a non-porous diaphragm or partition, composed in whole or in part of a body capable of acting as an electrolyte.

Apparatus for use in Electrolysis, I. L. Roberts, 442,333. Filed July 27, 1888.

Amplification of 442,332, covering the employment of two or more electrolytic partitions or diaphragms.

Electrolytic Apparatus, I. L. Roberts, 442,334. Filed Aug. 11, 1890.

In an electrolytic cell the inventor packs or embeds the anode in a material such as anthracite coal in the condition of an impalpable powder; uses an iron vessel or receiver as a cathode.

Claim 8 follows :

The combination, in a closed tank or vat, of an anode surrounded by a substance such as coal-dust, a gas-chamber or space above the same filled with granulated carbon, and a pipe leading therefrom for conveying off the gas, as set forth.

Electrolytic Apparatus, I. L. Roberts, 442,396. Filed March 14, 1889.

First claim follows :

An electrolytic apparatus consisting of a tank or vat divided with an electrolytic diaphragm or partition into two compartments containing conductors or electrodes, one of said compartments being adapted to contain the solution to be decomposed and the other or anode compartment filled with a finely-divided conducting substance, such as powdered coke or its equivalent, substantially as described.

Electrolytic Apparatus, I. L. Roberts, 442,594. Filed Oct. 22, 1890.

Claim 1 follows :

In a sealed tank or vat for electrolytic decomposition, the combination, with the anode embedded in or surrounded by a substantially non-porous electrolytic body, of an impervious cylinder around the anode, extending below the level of the solution, a layer of granulated carbon between the anode and the impervious cylinder above the level of the solution, and an outlet-pipe extending from the same.

Lamps and Appurtenances :—

Hanging Device for Electric Arc-Lamps, J. A. Lounsbury, 442,127. Filed July 23, 1890.

The lamp carries lamp-contacts of annular form ; the circuit contacts of the hanger comprise arms having bifurcated ends adapted to embrace the lamp-suspending medium and to engage the lamp contacts carried thereby. By the action of lowering, the line circuit is cut out of the lamp and automatically closed outside of it. The raising of the lamp to its normal position automatically re-establishes the circuit through it.

Device for Attaching Incandescent Electric Lamps to Gas Fixtures, N. Marshall, 442,270. Filed June 11, 1890.

A bracket for attaching incandescent electric lamps to gas fixtures, constructed from a single sheet of metal.

Incandescent-Lamp-Socket, G. W. Hunt and A. E. Rich, 442,287. Filed Oct. 29, 1890.

First claim follows :

The combination, with an incandescent lamp having a screw-threaded socket in its base and a flat eccentric contact-ring, of a socket having a threaded pin adapted to engage said threaded socket, and a sinuous concentric contact-ring, for the purpose set forth.

Pulley Attachment for Electric Lamps, T. H. Brady, 442,415. Filed July 14, 1890.

Consists of a pulley cover having a socket groove formed at its upper part, the cap-plate having the socket groove, and a shutting over flange on one of said parts to cover the seam at the socket groove.

Ceiling Block, H. T. Paiste, 442,451. Filed Oct. 14, 1889.

A design and construction of cut-out for pendant lamps.

Ceiling-Block, H. T. Paiste. 442,452. Filed Feb. 26, 1890.

First claim follows :

The combination in a pendant cut-out, of the base and terminals thereon, with a cut-out-carrying disc having terminals in line with the terminals on the base, with a cap resting upon the terminals of the disc, whereby on the securing of the cap to the base the terminals of the disc and plate are united, substantially as described.

Holder for Electric Lamps and Hoods, G. L. Batchelder, 442,472. Filed May 5, 1890.

A combined hood and lamp holder.

Claim 2 follows :

In a hood and lamp holder, the combination, with a hook on the support and a sliding bar on the hood provided with a hook having laterally-extending lugs, of a spring-guide extending over the hook provided with a central opening and inwardly-extending beveled portions, substantially as described.

Shade and Reflector for Electric or Other Lights, W. S. Fraser, 442,577. Filed Apr. 16, 1890.

An adjustable shade or reflector, capable of expansion or contraction, as desired.

Electric-Arc Lamp, W. B. Henderson, 442,580. Filed Aug. 4, 1890.

Object, to provide for the successive operation of four or five sets of carbons. Invention consists, in general terms, in providing two rotating hubs, each having a series of three or more radially-arranged carbon-holders, with mechanism for rotating the hubs and bringing the carbon-holders into proper relation to each other successively.

Electric-Switch, N. Marshall, 442,588. Filed June 11, 1890.

A revolving snap-switch for incandescent lamps.

Measurement :—

Method of and Apparatus for Measuring Electric Currents, S. C. C. Currie, 442,423. Filed Dec. 26, 1889.

Consists in actuating the indicator device by a resultant force due to two forces—one acting to repel and the other to attract—the ratios of the two forces being so related that as one diminishes the diminution is compensated by an increase in the other whereby a direct reading is obtained. The device is electro-magnetic, a movable armature being operated upon by the two forces.

Electric Meter, J. J. Wood, 442,501. Filed Nov. 3, 1888.

Current to be measured passes intermittently through a thermo-expansible strip or wire, being switched around it when the strip attains a certain expansion and again directed through it when it has contracted to a given length by cooling; the successive heatings being counted by suitable devices.

Claim 1 follows :—

In an electric meter, the combination of an elongated solid body arranged to be expanded by the heat generated by an electric current in encountering a resistance, a compensating expansible elongated body exposed to the same variations of surrounding temperature, a lever to which both said bodies are independently connected at different points, whereby the lever is moved by the elongating and shortening of both said bodies and its angular movement corresponds to their differential elongation or contraction, so that the compensating body corrects the disturbing effect of changes in surrounding temperature, and a switch for directing the current intermittently through said resistance, connected to said lever to be operated by the angular movements thereof.

Miscellaneous :—

Electric Gate, H. Gillette, 442,114. Filed July 19, 1890.

Gate operated by an electric motor and controlled through a circuit-closer operated by an electro-magnet.

Tanning by Electricity, L. A. Groth, 442,115. Filed May 19, 1888.

Consists in placing the hides and tanning liquid in a stationary tank, passing a current of electricity through the liquid and the hides, and moving the hides during the passage of the current, in planes transverse to and alternately toward and from a positive and negative electrode.

Electrical Vote Recorder, S. D. Locke, 442,126. Filed May 7, 1889.

Invention consists mainly in the peculiar arrangement of the manipulating apparatus with a view to securing them under lock and key from being tampered with during the absence of a member of a legislative or other assembly while a vote is being taken.

Insulating Covering for Pincher Handles, G. F. Virtue, 442,155. Filed July 31, 1890.

A rubber tube, shaped with a taper to adapt it to the ordinary form of handle, and relatively thin on one side, is slipped upon the handles of pinchers or pliers.

Cash Register, L. Ehrlich, 442,249. Filed March 21, 1890.

Indicating or registering mechanism actuated through electro-magnetic devices.

Mechanism for Controlling Torpedoes, &c., G. R. Murphy, 442,327. Filed Dec. 17, 1889.

Claim 2 follows :—

In torpedoes and other similar submarine vessels, the means for automatically releasing, under the application of a predetermined tension, the cable stored or coiled therein, and likewise for releasing the same through the agency of the electric motor controlling the valve admitting the fluid power to the engine, consisting of the cable provided with a bulb, a tube for the same, a resisting catch in the tube, a motor, and a connection between said catch and motor whereby the latter may release the former, substantially as and for the purpose set forth.

Metal Working :—

Process of Making Metal Tubes, etc., by Electro-Deposition, F. E. Elmore, 442,428. Filed Jan. 17, 1889.

Consists in revolving the cathode in an electrolytic bath while the current is passing, and simultaneously compacting the deposited metal by the action of a burnisher gradually moving from one portion to another.

Railways and Appliances :—

Circuit for Electric Railways, E. W. Sabolder, 442,140. Filed Sept. 22, 1890.

Consists of a series of electrical conductors, as say, plates or bars or rods, fixed in the ground in proximity to the track rails and in electrical contact with the latter, being practically an amplification of the earth contact.

Attachment for Span-Wires for Suspended Electric Conductors, F. Mansfield, 442,282. Filed April 26, 1890.

A device for raising and lowering span-wires. A polygonal-shaped block is mounted upon the outer face of each pole and adapted to be moved up and down the pole by rotation of the block, the span-wires being connected to the axis of the block so as to be vertically adjusted by their movements.

Charging Apparatus for Switch and Signal Mechanisms, J. G. Schreuder, 442,339. Filed July 16, 1890.

Electro-magnetic devices employed to control the operation of valves in a system of switching or signaling through the means of fluid-pressure.

Railway Car Telegraph, C. R. Arnold, 442,347. Filed July 13, 1889.

Apparatus and devices for signaling to the engineer from any car of a train, and for answering and repeating from the locomotive. Provides for a continuous signal to be given by a vibrating bell on the locomotive in case a train should part at any point. Includes arrangements for supplying the train circuit from a dynamo carried on the engine. Makes use of air or steam pipes as conductors for the circuit in part.

Electric Traction-Increasing System, M. W. Dewey, 442,365. Filed July 28, 1890.

Consists in a stationary source of heavy current or currents connected to the rails of the track and two or more wheels of the vehicle, and one or more axles or other low-resistance conductor extending between the wheels to complete the circuit through the rails.

Electric Railway, M. J. Wightman, 442,407. Filed April 1, 1885.

Object is to economize in the weight of conductors and to secure independence of action in the motors on different lines or sections of lines of rails. The invention is essentially an improvement or amplification of the three-wire method of distribution. The system of connections constitutes in effect a series multiple-arc system, in which the compensating action of the well-known three-wire system obtains. It is in substance a 4-wire system, or a 3-wire system extended to contain a third set of apparatus supplied in multiple to one another, but in series with the two other sets or sections.

Trolley-Wire Hanger, H. H. Luscomb, 442,446. Filed Sep. 19, 1890.

A design and construction for a hanger adapted to grasp firmly and securely a trolley-wire without employing solder.

Slot-Switch for Conduit Systems of Railways, F. O. Blackwell, 442,475. Filed Oct. 27, 1890.

Claim 1 follows :

In a conduit-switch, the combination of a movable slot-switch with a swinging hanger or hangers furnishing means of support therefor, for the purpose set forth.

Secondary Batteries :—

Method of and Apparatus for Manufacturing Secondary-Battery Electrodes, J. G. Johnston, 442,187. Filed Aug. 15, 1890.

Relates to the class of electrodes in which the active material is contained in an external envelope or supporting case.

First claim follows :—

The process of forming secondary-battery plates having a perforated metallic envelope or supporting case, which consists in separately striking up and perforating the metallic sides of the plate, and then assembling said sides and the active material in a dry state upon the punching-die, and finally compressing the whole together in said die, as and for the purpose intended, substantially as described.

Secondary Battery, J. K. Pumpelly, 442,390. Filed Feb. 10, 1890.

Consists essentially in arranging the positive and negative plates edge to edge rather than face to face. Shows the negative electrode in the form of a rectangular frame, and the positive electrode as a rectangular plate of suitable size to be suspended or held within the opening of the negative electrode and in the same plane with it.

Seconday Battery, J. K. Pumpelly, 442,391. Filed March 24, 1890.

The electrodes are separated and held apart by cellulose and wood-pulp fiber.

Telegraphs :—

Telegraphy, E. B. Ives, 442,267. Filed Feb. 24, 1890.

Applicable to synchronous multiplex systems, and consisting chiefly in devices for duplex working.

Relay, J. G. Schreuder, 442,338. Filed July 16, 1890.

The claim follows :

In a relay, the combination of electro-magnets and a gravity-armature formed of resilient material, the pivotal support and contact-point of the armature being arranged in a plane below the poles of the magnets, whereby the armature is placed under tension when attracted by the magnets, substantially as set forth.

Printing-Telegraph, W. W. Taylor, 442,497. Filed May 26, 1890.

First claim follows :—

A printing-telegraph consisting, essentially, of type-writers electrically connected and having means for operating the type-levers thereof, a paper-supply roll mounted in the type-writer carriages and having means for feeding the paper through the type-writers, a box mounted on the type-writer carriages and having a suitable opening therein, a vertically-movable two-edged knife adapted to cut off the paper at a desired time and place, means for moving said knife, and a guide fixed to the back of the knife and adapted to align with the opening in the box, substantially as described.

Telephones and Apparatus :—

Multiple Telegraph or Telephone, A. M. Rosebrugh, 442,139. Filed June 6, 1887.

Object is to increase the working capacity of a telephone circuit, to facilitate long distance telephony and to provide for duplex working.

First claim follows :—

The combination, in a system of telephonic communication, of a metallic or double parallel line circuit extending between two or more stations, local circuits including telephone apparatus connected by means of induction coils with both sides of the said double line main circuit, and earth branches including telephones connected with the said metallic circuits at the terminal stations thereof and at a point between the said induction coils, whereby the stations inductively connected with the double-line circuit may be enabled to communicate with one another, to the exclusion of the earth branch stations, and vice-versa, as hereinbefore described.

Multiple Switch-Board System, C. E. Scribner, 442,143. Filed Oct. 15, 1888.

A feature of the invention lies in the discovery that the introduction of a retardation coil into a ground branch extended from one side of a metallic

circuit overcomes the harmful effect of such grounding by shutting off the flow of induced currents, which would otherwise disturb the telephone.

Tenth claim follows :—

The combination, with two metallic telephone line circuits looped together at one of several multiple switch-boards with which said lines are connected, of a branch circuit from the side of the united circuit, said lines connected with the test-pieces of the switches, said branch, including a self-induction coil and battery, and a corresponding branch circuit to ground from the other side of said metallic circuit through a corresponding self-induction device, whereby the said circuit is balanced with respect to inductive effects, substantially as and for the purpose specified.

Telephone Exchange Apparatus, C. E. Scribner, 442,144. Filed Nov. 23, 1888.

For use with metallic circuit. Provides for uniting any two circuits without including in the united circuit any electro-magnetic devices other than the telephones of the subscribers thus connected, while at the same time providing for signals between the central office and subscribers for connections and disconnections.

Multiple-Switch-Board System, C. E. Scribner, 442,145. Filed Nov. 23, 1888.

Relates to the class of multiple switch-board circuits in which metallic circuits and single or grounded circuits are connected with the same exchange. The invention is designed to avoid the necessity of employing special test-plugs at the central station in adapting to the service of mixed metallic and grounded circuits, the methods of patent number 412,143 above.

Telephone Exchange Apparatus, C. E. Scribner, 142,146. Filed Dec. 10, 1888

Object is to loop the different lines together without including any unnecessary resistance in the talking circuit.

First claim follows :—

The combination, with two subscribers' stations, of their metallic-circuit telephone-lines looped together to form a single metallic circuit for conversation free of resistance, except the telephones, the different sides of said metallic circuit being provided with a branch circuit, each such branch circuit containing the individual annunciator of its line, each annunciator constructed to operate as a self-induction coil, and each of said branch circuits being connected to a ground branch, including a battery.

Telephone Toll-Station, J. W. Vaughn, 442,342. Filed April 24, 1890.

Apparatus for indicating automatically to a central station operator the fact of the deposit and the denomination of a coin placed in the slot at a toll station.

LEGAL NOTES.

LEROY B. FIRMAN AND THE WESTERN ELECTRIC CO. vs. THE NEW HAVEN CLOCK CO.—DECISION IN FAVOR OF DEFENDANT ON THE MULTIPLE CALL BOX PATENT.

This was a bill in equity to prevent the alleged infringement of the fifth claim of letters patent, No. 192,644, dated July 3rd, 1877, granted to Leroy B. Firman, and owned by the Western Electric Co., for improvements on automatic signaling apparatus, used in the system known as the "district telegraph system," in which "each station is designated by a number, and the apparatus is constructed to write that number as a 'call' and subsequently to write any one of several signals, at the will of the operator."

The apparatus was an improvement upon the device described in letters patent No. 185,455 to G. S. Ladd and S. D. Field, which contained one circuit breaking wheel.

The improvement consisted in two wheels, instead of one, which automatically and successively communicated to the central office the two sets of signals.

The fifth claim, and the one which is said to have been infringed, is as follows :

"5. The combination, with a call writing wheel, of a signal writing wheel, moved by the same power, when the latter is provided with a number of equal-spaced teeth, which write the signal desired by making a certain number of equal-spaced impulses, substantially as specified."

The defendant uses an apparatus which is described in letters patent No. 321,073, dated June 30th, 1885, to Frank B. Wood. It produces a compound signal by the joint action of two wheels. It has "two signal wheels which are geared to each other and to the clock work, so that they both move simultaneously and in unison during the time that both parts of the compound signal are being transmitted ; while thus in motion, they are acted upon by opposite ends of the same electrical contact spring."

The plaintiffs claimed that the equivalent of the Firman signal wheel was the small wheel of the defendant, which transmits by a series of equally-spaced impulses, and that the equivalent of the call wheel is the large wheel of the defendant, which has its periphery so cut away as to determine the numerical signal which is sent, notwithstanding that the actual transmission of the signal is performed by the other wheel, and that thus the defendant's device contains the call wheel and the signal wheel of the fifth claim.

Judge Shipman, in his decision, says : "If a literal construction is to be given to the fifth claim, and the requisites of infringement are a signal writing wheel, with equally-spaced teeth, which makes equally-spaced impulses, and a call writing wheel in combination, regardless of the manner in which these two wheels operate to produce the result, the remaining element being power operating the two wheels in such a manner as to transmit the compound signal at one operation, then the defendant infringes.

"In my opinion, such a broad construction cannot be given, but the scope of the patent must be confined to mechanism substantially such as is described in the patent, viz., two wheels, moving by the same power, in succession and automatically, one of which produces a part of the signal by its sole action, and the other of which produces the other part by its sole action. It is true that the Firman invention was the first one having two wheels which did both parts of the work automatically, but this step cannot give the device the character of a primary invention and permit the inventor to include within his patent wheels which differ so wide from his apparatus as do the double wheels of the Wood patent.

"The bill is dismissed."

George P. Barton and Wm. Edgar Simonds, for the plaintiffs.
Harry M. Turk and Arthur v. Briesen, for the defendant.

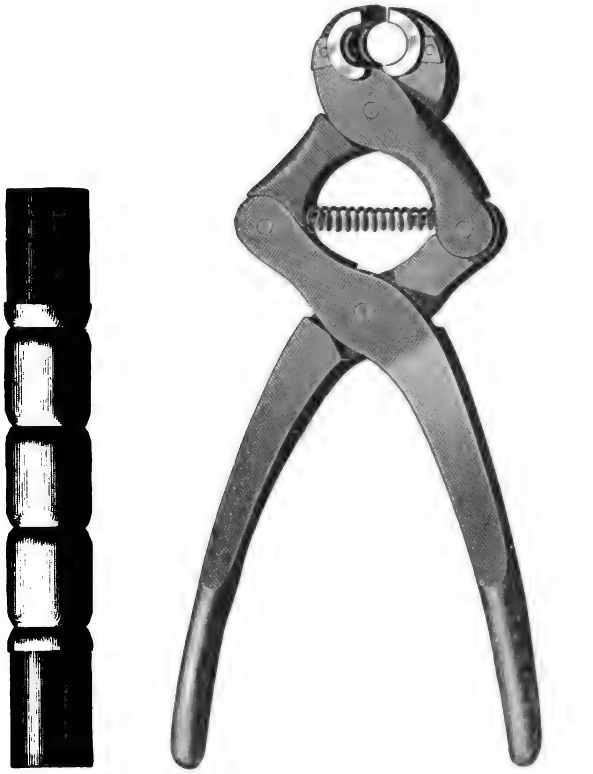
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

NEW DETAILS OF THE INTERIOR CONDUIT SYSTEM.

The superiority of the Interior Conduit system, not only for all classes of electr c light wiring but for electric bell and annunciator wiring a s well, has been demonstrated and is now universally conceded.

The Interior Conduit & Insulation Company, the pioneers and sole manufacturers of interior conduits, are continually striving to simplify the constructionary methods of their admirable system and to cheapen the cost of their goods. One of the most striking examples of their energy in this direction is to be found in their new coupling or joint which we illustrate in the accompanying engraving, Fig. 1.



FIGS. 1 AND 2.—NEW "INTERIOR CONDUIT" JOINT AND JOINTING TOOL.

The greatest amount of labor expended in the installation of the system is at the most vital point of the whole, that is, upon the joint or coupling.

The methods heretofore employed for making joints have been found satisfactory, but in order to insure perfect work great care had to be exercised on the part of the workmen, and it is with the idea of remedying this that the new coupling has been designed and placed upon the market.

The new joint will supplant and entirely dispense with the use of the threading tool, threaded coupling and cementing compound. The sleeve is made of soft galvanized iron and, being of a slightly larger diameter than the tube itself, fits snugly upon it. The tool, Fig. 2, which is made in the form of a pair of pliers, serves to

press the two slight corrugations upon the outside of both halves of the sleeve and into the body of tube, but does not in the least injure the latter or alter its internal diameter at that point. Joints so made are impervious to moisture and have great strength.

By the new method, joints may be made upon the floor or bench and the lengths of the tubing lifted with safety to the wall or ceiling without fear of straining or opening the joints. It is confidently believed that the new tool is destined to become an important factor of every wireman's kit of tools.

MR. HENRY HUTTON.

Mr. Henry Hutton, of Baltimore, and formerly connected with the Western Electric Co., of Chicago, intends resuming his old line of business as a consulting electrical engineer, and he will establish himself at Tacoma, Wash., within the next ten days. Mr. Hutton will be glad to receive at that place catalogues of light and power supplies, and to represent reliable houses.

ELECTRICAL SUPPLY CO., CHICAGO.

The above house has just issued a catalogue of Edison specialties and a circular of Edison incandescent lamps. The specialties include meters, switches, holders, insulating joints, sockets, plugs, cut-outs, &c. The company is now making a feature of handling these Edison goods.

MR. W. J. HAMMER.

A man highly original in his ideas and methods, Mr. W. J. Hammer, who has recently established himself in the Temple Court annex, this city, has chosen a unique manner of preparing and issuing his professional circular as a consulting and supervising engineer. It is by all odds the most interesting thing of the kind that has ever fallen into our hands, and Mr. Hammer reaches his result without any sacrifice of dignity. For the past 12 years he has been actively engaged as an electrical engineer, and in many fields, particularly those of light and power, has been a pioneer. Associated with Mr. E. H. Johnson he started in London the first incandescent station in the world, and he has since had charge of large exhibitional plants in Europe and America. The pamphlet illustrates his career admirably. It is made up of testimonials of a very flattering nature from such men as T. A. Edison, E. H. Johnson, Elihu Thomson, F. J. Sprague, H. M. Byllesby, Wm. Wallace, F. S. Hastings and F. R. Upton, and interspersing there are a number of fine engravings, each of which has some special point of interest. Thus for example there are views of the Edison exhibit at Paris in 1889 ; the Cincinnati exposition of 1888 ; the Crystal Palace electrical exhibition, London, of 1882 ; and the electrical exhibition at Philadelphia in 1884. Another picture shows the beautiful Ponce de Leon Hotel at St. Augustine where a plant was set up driven by an artesian well. There is also some very interesting text and data, and the pamphlet is just the kind of thing that one preserves for its intrinsic value. Mr. Hammer includes also a photograph of his wonderful collection of incandescent lamps, and has sensibly given all the testimonials in fac simile. The pamphlet is elegantly printed. Mr. Hammer, in a brief introduction, announces his intention of doing only consultative and supervisory work.

MR. E. G. BERNARD.

One of the most active and successful of the younger electrical engineers is Mr. E. G. Bernard, who after a long period of service with the Sawyer-Man and Westinghouse Companies, has recently started out on his own account, with what is practically a new system of electric lighting. He has established his headquarters at Troy, and the factories are located at Amsterdam, N. Y., and Warren, O. His experience of 11 busy years, during which time he has put more plants in silk mills and knitting mills than any other man in America, has taught him the points to aim at in dynamo construction, so as to secure continuity, stability and economy in operation, and the machines he is now building and installing are models of their class. As to his plants, we can speak of their thoroughness and high finish from some six years' acquaintance with his work. Mr. Bernard, who, by the way, is a member of the American Institute of Electrical Engineers, has not only embodied his own ideas in the machines, but has had their proportions thoroughly worked out with expert help, and he is guaranteeing them, under bond if desired, to be the equal in material, workmanship and automatic operation of any in the market. Mr. Bernard is already supplementing his record of 300 installations of other systems by a large number of "E. G. B." plants, and during the last 40 days has sold the following: Howgate, McCleary & Co., Amsterdam, N. Y., 300 lights; Packard Electric Co., Warren, O., 200; Utica, N. Y., Pipe Foundry Co., 100 incandescents and 4 arcs; Petit Bijou Piano Co., St. Johnsville, N. Y., 100; Roth & Englehardt, St Johnsville, 300; Standard Furniture Co., Herkimer, N. Y , 150; H. M. Quackenbush, 100; Henry Bell & Sons, Milton, N. Y., 100; Williams & Powers, Cohoes, N. Y., 100; Hudson Valley Knitting Co., Waterford, N. Y., 150; Myers & Parker, Fultonville, 100; besides a U. S. plant of 100 lights in F. O. Pierce & Co's. paint works, Brooklyn, N. Y. On Dec. 10, he closed a contract for his fifty-second knitting mill. It will be seen that Mr. Bernard can make sales despite the dull times, but even the above record is incomplete as he has also, in addition, placed over 50 firms and corporations on his books with orders for supplies, watchman's time detectors, etc. He expects also to have a general supply store running in Troy by January 1, and will then make his permanent change of address to that place. Mr. Bernard is doing all this work on the most conservative basis, and is in shape to carry on an enormous business, which will certainly not be lessened by the promptness with which he fills orders—one plant of a 100 light machine and 50 lamps having been put in complete in 2 days and another plant of a 100 light machine and 100 lamps in 4 days.

JAMES H. BATES.

The above named gentleman, who was formerly with the Sprague Co., afterwards with the local Edison Co., of Philadelphia, and more recently with the Fort Wayne Electric Co., has now located himself in New York, with headquarters at Moore Bros., 106 and 108 Liberty street, where he will carry on a business in general electrical supplies and will handle electric motors. His activity, knowledge of the trade, and wide acquaintance should bring him plenty of business.

NEW ENGLAND TRADE NOTES.

MR. F. H. LOVEJOY, for many years connected with the Wainwright Manufacturing Company of Massachusetts, has resigned his position with that company. Mr. Lovejoy is well known in the vicinity as an energetic salesman and has not yet decided where he will be located in the future.

THE STANDARD ELECTRIC CO. OF VERMONT have sold a 500 light plant to the Lebanon Building and Power Company of Lebanon, N. H.

CLAFLIN AND KIMBALL.—The business of the Mather Electric Co., and the Perkins Electric Lamp Co., conducted in New England through their agents, Messrs. Claflin & Kimball, has increased so rapidly that they have been obliged to remove to larger offices in the new building of the Shoe and Leather Association, on Bedford and Kingston streets, Boston. This change, made necessary by the rapid expansion of their business, provides the above company with very convenient and accessible offices. The business of the firm has more than trebled each year for the past three years, and this year they have sold and installed apparatus for incandescent electric lighting in isolated plants alone, nearly 9,000 lights since the 1st of February.

THE PERKINS ELECTRIC LAMP CO. are now manufacturing about 5,000 lamps a day, and are still away behind on orders.

WESTERN TRADE NOTES.

MR. WM. B. KNIGHT the prominent electric railroad contractor of Kansas City, was badly scalded in the recent accident on the Wabash road at Jacksonville.

THE ILLINOIS ELECTRIC MATERIAL CO., Rookery, Chicago, have just been appointed General Western agents for all the new and valuable specialities of the well-known Star Electrix Company, of Philadelphia. Amongst others those of special merit are the new electric switch and cut-out, and also a highly ingenious and effective lamp socket which is very readily wired and remarkably handsome in finish and very durable.

MR. THOMAS WRIGLEY, 85 Fifth avenue, Chicago, whose ingenious vertically adjustable dynamo support was fully illustrated and described in the last issue of THE ELECTRICAL ENGINEER, has furnished the city for use in their power house, at Troop and Van Buren streets, ten of his supports, where they are doing excellent and most efficient service. Those who are running belts vertically to connect the engine pulley with that of the dynamo should provide themselves with this very useful device.

MR. H. K. GILMAN, who has become so widely and favorably known amongst the electrical fraternity all over the country from his long connection with the Northwest-Thomson Houston Electric Company as its assistant general manager, and to whose work the prosperity and extensive business of that flourishing concern is largely due, has now come to reside in Chicago and take the managership of The Great Western Electric Supply Company, in the carrying out of which he is certain to achieve the most signal success. Mr. H. K. Gilman was an officer in the navy and has a host of warm friends in the service, who will be glad to know of his many brilliant results in the field of electrical work. He is another of the navy men who have made their mark in the service and later turned their attention to the electrical profession with the most happy results, seeming to be peculiarly fitted to it by their early naval training. The list now includes such men as Shallenberger, Gilman, Dana Greene, Louis Duncan, Gilbert Wilkes, Wood, Cahoon, Colvin and others.

MR. S. W. HUME, special agent of *Power-Steam*, was a visitor to Chicago last week. Mr. Hume was busily engaged while here in looking up the numerous friends and patrons of his journal.

THE
Electrical Engineer.

VOL. X. DECEMBER 24, 1890. No. 138.

SOME MEASUREMENTS THAT ARE CONVENIENTLY ACCOMPLISHED IN PRACTICE BY THE WESTON HIGH RESISTANCE VOLTMETER.

BY OSBORN P. LOOMIS.

IN the following I have attempted to give a practical description of some methods of applying a high resistance voltmeter to the ordinary measurements that occur in the every day life of the electrical engineer. It is attempted to make them as clear as possible, and probably more so than is necessary to many, who may also have used the same method with various modifications; to others, however, they may prove of interest and value.

The first application I will mention is that of measuring approximately the insulation resistance of line work, etc. In the diagram, Fig. 1, is shown a system of wiring in which we will suppose there is a leak at X. By providing a ground at another suitable place, and attaching the voltmeter as shown, take a reading on the ground circuit, and call it V. Then take the full E. M. F. of the line, calling it

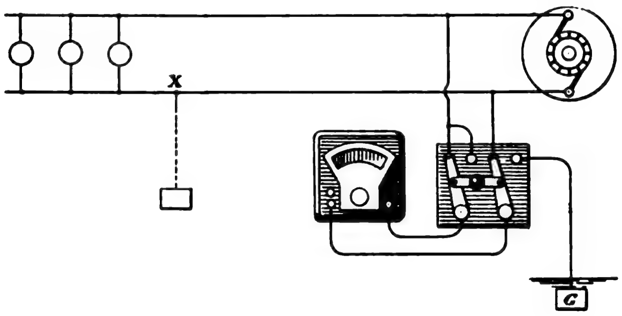


FIG. 1.—LOCATING A GROUND LEAK.

V'. Knowing the resistance (R) of the voltmeter, the resistance of X or the ground leak will be $\frac{V' R}{V} - R.$

The following is an example:
Ground reading, 20 volts (V). Line reading, 120 volts (V'). Voltmeter resistance, 16,660 ohms (R).
Applying the formula we get,

$$\frac{120 \times 16,660}{20} - 16,660 = 99,960 - 16,660 = 83,300 \text{ ohms.}$$

The line insulation resistance is therefore equal to 83,300 ohms.

In this manner insulation resistances may be measured up to one megohm and at any time while the circuits are in operation, the convenient connecting switches being permanently arranged on the switchboard. In this way interesting data can be obtained regarding the effect of different states of weather on the line.

This principle can be applied to the measurement of the resistance of the human body, and it is a much more desirable method than by the Wheatstone bridge. Fig. 2 shows the arrangement in detail.

Two glass jars are provided, each containing a weak solution of caustic potash, and copper plates connected in series with the voltmeter and dynamo, or a battery of small storage cells to be described later. It is desirable to run the voltage up as high as the subject can endure, which may be 140 volts. Then the jars are short-circuited by the key and another reading is taken. Calling the first

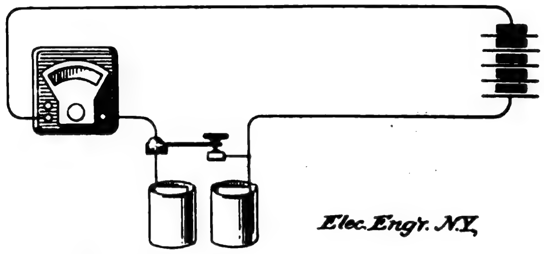

FIG. 2.—MEASURING RESISTANCE OF THE HUMAN BODY.

reading V and the second reading V', and the resistance of the voltmeter (R) the result is found as in the previously mentioned insulation resistance, viz.: $\frac{V' R}{V} - R.$

Here is an example:
Subject in circuit, 140 volts (V).
Voltmeter alone, 149 volts (V_1); resistance of voltmeter, 16,660 ohms (R).
Applying the formula,

$$\frac{149 \times 16,660}{140} - 16,660 = 1,731 - 1,660 = 1,071 \text{ ohms.}$$

If the circuit-closing key is opened while the subject's hands are in the solution, the sudden shock will be very unpleasant; but by immersing the hands while the current is on it can be endured quite readily, as the volume of current will probably not exceed 9 milliamperes with 150 volts on the voltmeter. It is, of course, obvious that a high resistance voltmeter is absolutely necessary in these measurements; in fact, the higher it is, the better.

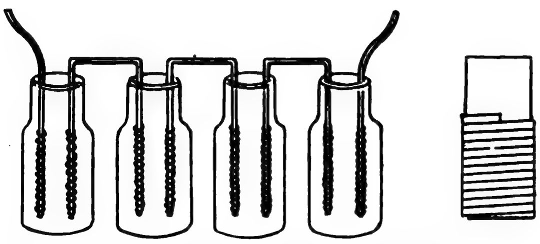

FIG. 3.—SIMPLE STORAGE BATTERY FOR TESTING.

Right here I will mention a simply made storage battery for these and other measurements. Procure about 72 large-mouthed bottles, about 2½ inches in diameter and 6 or 8 inches deep. Make the plates of lead strips with other very narrow strips of lead wound around the portion which is immersed in the acid. To save the trouble of numerous connections, make one strip long enough to reach over into both bottles with the afore-mentioned wound portion on each end. The arrangement is shown in Fig. 3.

They are usually charged in two rows in multiple, as ordinary incandescent circuits do not give the requisite E. M. F. in series. A switch is used, Fig. 4, which quickly throws them in series and multiple with the discharging circuit. One of the uses of this battery is in photometry work; as the current gradually falls, it is started at a higher E. M. F. than the standard and the screen watched when the balance is obtained; then a signal is given and the E. M. F. and current are read by other parties, so that the efficiency for any given candle-power is obtained.

We now come to the internal resistance of batteries, in which no ammeter is required, but a standard resistance, Fig. 5, made of heavy German silver or platinoid wire, about No. 7 or 8 gauge. Ten spirals wound right and left handed and placed alternately, to avoid magnetic effect as far as possible, are arranged to be connected in series or multiple by large brass screws. By this arrangement it can be measured in series or multiple and any error can be found that might exist where only the low resistance could be measured. This resistance is conveniently adjusted to 1/100 of an ohm in multiple; in series it would be 1 ohm measured in legal units. In this combination a variety of work can be accomplished.

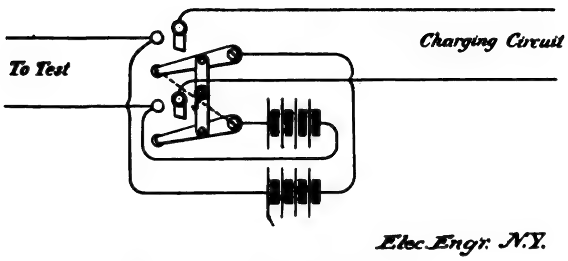

Fig. 4.—Charging Switch.

To measure the resistance of an accumulator, connect up as shown in Fig. 5. Take a reading of the E. M. F. with the cell on open circuit and call it V; then close the circuit through the standard resistance and call the decreased E. M. F., V'. Then the internal resistance of the accumulator is $\dfrac{V - V'}{\dfrac{V'}{\text{Stand. } R}}$

The following is an example:

E. M. F. on open circuit, 2.15 volts; E. M. F., discharging through standard resistance of .01 ohm, 1.43 volt. Then, by the formula, the internal resistance of the cell is,

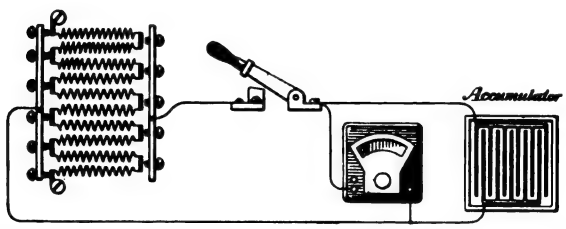

Fig. 5.—Measuring The Internal Resistance of Batteries.

$$\frac{2.15 - 1.43}{\dfrac{1.43}{.01}} = \frac{.72}{143} = .005 \text{ ohm.}$$

In this experiment the connections and conductors must be as large as possible so as to avoid any errors from that source; but they may be obviated entirely by taking the P. D. directly off the terminals of the battery and the terminals of the resistance beyond the point of connection. This is only an application of Ohm's law pure and simple, and it is because of its simplicity that makes it so valuable.

I might mention that in this method it is necessary to have the double-reading voltmeter, but the internal resistance of a group of cells can be found quite readily by the single-reading voltmeter, and then the average resistance, of course, can be found. Say, we have a group of 10 cells and the standard resistance is changed to 1 ohm. If we get 21 volts on an open circuit and, closing the circuit through the resistance, it drops to 20 volts, then the internal resistance of the group of 10 cells will be,

$$\frac{21 - 20}{\dfrac{20}{1}} = \frac{1}{20} \text{ or, .05 ohm, total resistance.}$$

$$\text{Hence, the resistance of 1 cell is } \frac{.05}{10} = .005 \text{ ohm.}$$

The internal resistance of batteries can also be obtained by the charging current as well as the discharging; for, suppose in charging 25 cells we observe by an ammeter 30 amperes flowing in the circuit and their P. D. is 56.8 volts. Upon taking off the current and observing *the instant* the needle stops falling (the instrument being so "dead beat" that there is very slight oscillation after the current is disconnected) it shows 50 volts; then the internal resistance is,

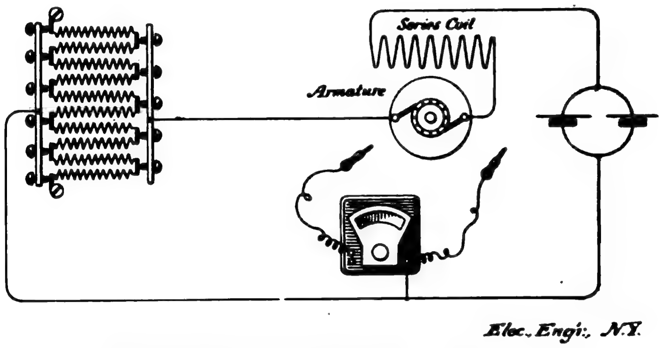

Fig. 6.—Measuring Low Resistances.

$$\frac{56.8 - 50}{\dfrac{50}{1}} = \frac{6.8}{50} = .136 \text{ ohm, total; or } \frac{.136}{25} = .005 \text{ ohm per cell.}$$

This method is not as accurate as the preceding one, but can be used in the case of primary batteries which polarize rapidly on a discharge.

The next application is to the measurement of low resistances by the low-reading scale of the voltmeter, such as armatures and series-coils of compound dynamo machines. As shown in Fig. 6, put the standard resistance of .01 ohm in series with the armature, series-coil and an accumulator, or, better, several accumulators in parallel. Take the P. D. of the standard resistance and call it V; then the P. D. of the armature, calling it V'. The resistance of the armature will be

$$\frac{V' \text{ (Stand. } R.\text{)}}{V}$$

Example:

P. D. at Stand. $R.$ = 2.35 v. (V); P. D. Armature = 3.15 v. (V')

Applying the formula,

$$\frac{3.15 \times .01}{2.35} = .013 \text{ ohm.}$$

The resistance of the series-coil is found in the same way. To check errors from the diminution of current between readings, they should be gone over twice. This same stand

ard resistance can be used to measure currents of comparatively large magnitude, say, up to 400 amperes. It is best to take the readings as quickly as possible to avoid the temperature error, which, while not large, it is better to avoid as much as possible.

In this measurement the P. D. observed, divided by the standard resistance, equals the current. For example, suppose we obtain the P. D. of 2.55 volts and the standard resistance was .01 ohm; there would then be 255 amperes flowing in the circuit. I find this very useful in calibrating ammeters, using 6 or 8 cells of accumulators of large type connected two in series and three or four in multiple. In this way it is possible to obtain 300 amperes long enough to secure a reading. Smaller currents may be obtained by a resistance introduced in the circuit, generally a german silver strip with a heavy sliding contact.

For reading for 1 to 15 amperes, use the coils in the resistance put in series, and the P. D. (if the resistance is 1 ohm) will be in terms of the current. It is seen that quite a range of work can be obtained. Sometimes it is desired to read a higher E. M. F. than the voltmeter is graduated to do. By introducing the resistance, of course, the reading is reduced. Add the resistance of the voltmeter (with which they are all accurately marked) and the reading will be halved. This resistance being so high is the most troublesome to make. A very convenient way is to take a piece of ground glass marked with graphite and measured

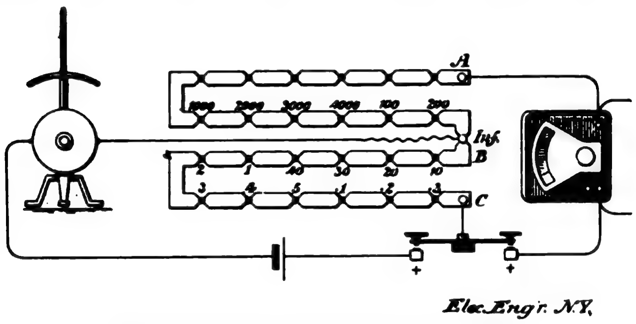

FIG. 7.—CALIBRATING THE VOLTMETER.

by the Wheatstone bridge and finally adjusted with the voltmeter.

To verify the reading of the voltmeter at any time, or, in other words, to compare it with a standard cell, take an ordinary resistance box (legal or B. A. ohms), and connected as shown in Fig. 7, using two keys (generally those on the box), the first one to close the circuit through the total resistance from A to C, and the other to close the standard cell through the galvanometer. If we are reading about 100 volts, and unplug 5,000 ohms between A and B, then we unplug enough between B and C to obtain a balance in the standard cell circuit. It is advisable to have the least possible current flow through the standard cell, and at the commencement it is convenient to know approximately what resistance to unplug between B and C so that the balance will be nearly obtained upon the first trial. For example, suppose we have unplugged 5,000 ohms between A and B and we observe that the E. M. F. to be tested is about 112 volts and the standard cell is 1.444 volt. Multiply the 5,000 by 1.444 and divide the product by 112—1.444; the result will be approximately the number of ohms to unplug from B to C. Thus,

$$\frac{5000 \times 1.444}{112 - 1.444} = \frac{7220}{110.556} = 65.3 \text{ ohms.}$$

This is merely to save the trouble of hunting around after a balance, as well as to avoid unnecessary current passing through the standard cell; after this is done, however, we disregard the reading on the voltmeter and fall back on the standard cell E. M. F. as the standard. When this is done the total E. M. F. will be $\frac{(R + R')\,V}{R'}$, where R equals the resistance between A and B; R', the resistance between B and C; and V, the E. M. F. of the standard cell.

Example: Resistance unplugged between A and B, 5,000 ohms; resistance unplugged between B and C, 66 ohms.

Applying the formula, $\frac{(5{,}000 + 66)\ 1.444}{66} = 110.7$ volts.

In this method it is necessary to observe the position of the needle very carefully at the instant the balance is obtained, and not observe one and then the other with any large interval of time, for, with a sensitive galvanometer changes of .1 volt in 100 are easily detected. The connection at INF. is made by a cord and plug, the plug being made to fit the holes which are on the box. By this means this contact can be made at any point desired.

I will add to this article some points of interest to operators generally, as they may obviate some of the troubles that have come to others. This instrument, sensitive as it is to $\frac{1}{10}$ of 1 per cent., should receive a corresponding amount of good usage. No one would think of slamming a good watch around; yet the jewels and pivots of these instruments are as carefully made and adjusted as in a fine watch.

Being affected by magnetism, close proximity to all powerful magnetic fields should be avoided. Of course a nice voltmeter looks neat on a switch-board, but, surrounded by bus bars carrying heavy currents, that is far from the best place for it. It is better to put it in a place by itself at least 12 feet away from the conductors and dynamo, in fact, the further, the better, to secure accurate results. As only small wires are necessary to connect with the mains the above arrangement will cause little inconvenience. Of course it is unnecessary to state that it should never be carried near a dynamo, much less laid on the top of one, while in operation.

I will also call attention to the low temperature error that exists with this instrument. There being no copper wire of any consequence in the circuit, the current is so very small on account of its high resistance, that it can be left on the circuit indefinitely; it can also be used in the ordinary differences of surrounding temperature, with only an error of a fraction of 1 per cent. I will state that some of these instruments, after having been in use for three years, have been calibrated and agreed perfectly with the original, showing that, when handled properly, their permanency is unaffected.

NOTE ON PROFESSOR SHELDON'S EXPERIMENT ON THE "MAGNETO-OPTICAL GENERATION OF ELECTRICITY."

BY C. F. BRACKETT AND S. T. DODD.

WE have endeavored to produce an electric current in the manner described by Professor Sheldon in the *American Journal of Science*, September, 1890, page 196[1]; and we have also endeavored to produce it by other, similar means which his experiment suggested; but with entirely negative results.

We first followed as nearly as possible the arrangement of Professor Sheldon; the only essential change which we made was in the substitution of a glass tube for the brass one on which the coil was wound. The experiment was carried out with the result that faint musical sounds were heard in the telephone, which could be referred either to the action of the arc lamp or to the moving machinery. On interrupting the ray of light no change whatever was produced.

We next discarded the oscillating apparatus and substituted one by means of which we could rotate the Nicol prism about 200 times per second. For, if Professor

1. THE ELECTRICAL ENGINEER, December 3.

Sheldon's reasoning be correct, a rotation of the plane of polarization through 360°, 200 times per second, ought to produce an electromotive force higher than would be produced by the oscillation of the mirror reflecting the beam 300 times per second. We failed, however, to obtain any indication of a direct current by the use of a delicate galvanometer, or of an interrupted current by means of a telephone, when the ray of light was rapidly and periodically interrupted.

In the third place, if an electromotive force can be induced by mechanically superimposing a third rotation upon the two existing rotations which are regarded as the equivalent of a plane polarized ray, then a still greater electromotive force should be induced by suppressing one of the original rotations; that is to say, by using circularly polarized light. Accordingly this plan was employed and with negative results.

It occurs to us to remark in reference to the general subject:

(1.) That an oversight has been made, by Professor Sheldon, in a matter of such extreme delicacy, in the employment of a conducting core for the helix instead of a nonconducting one.

(2.) That an arc light is wholly unsuited to be employed in such an investigation. Finding that the currents set up in the helix, by the variations of the magnetic field about the arc, were sufficient to mask any effect that we might hope for, we were forced to employ the calcium light instead.

(3.) Professor Sheldon does not state the material of which his mirror was made. If it was of glass, Fresnel's formulæ for the reflection of polarized light would show that, at an incidence of 80° to 85°, a rotation of the mirror through an angle of 45° would only produce a rotation of about 10° in the plane of polarization of the reflected beam. If the mirror was silvered, according to Jamin's experiments on metallic reflection, the reflected beam would be plane polarized only in case the angle between the planes of polarization and reflection were 0° or 90°.

Electrical Laboratory,
Princeton, N. J., Dec. 18th, 1890.

TRANSMITTING PICTURES ELECTRICALLY.

BY W. S. EATON.

Some few months ago in the electrical journals appeared a new method of sending pictures by telegraph. Briefly stated, the process was to divide the picture to be sent into squares, and each square was numbered to correspond with a paper similarly prepared and to be used at a distant point to draw upon, according to the direction sent from the transmitting station by the number communicated.

The example illustrated in the article alluded to, particularly impressed the writer with its very mechanical appearance. Every line was necessarily a straight one, and as the outline, only, of the picture could be thus communicated, it seemed to him that the idea, although an exceedingly good one, was altogether inadequate for practical purposes, to say nothing of its utter impracticability as applied to portraits.

When the Bell telephone was brought out as a commercial success, it opened up a vast array of new possibilities. It was simple enough, too; but it is singular, indeed, that these very simple things lie so long undiscovered.

I have apparently digressed from the subject and started to write on telephones, but this digression is more apparent than real, since the method of transmitting pictures electrically, which I shall venture to propose, is based upon principles inseparably connected with telephony.

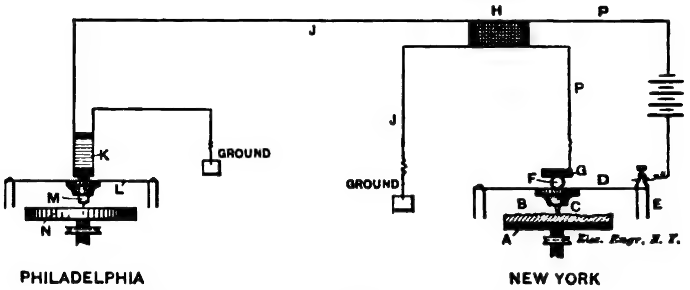
In order to make clear my idea, I must be permitted, for another brief interval, to depart from electricity and take up the wonderful chemical changes brought about by the action of light in the art of photography.

If we mix in proper proportion bichromate of potassium and gelatine we get a mixture that is highly sensitive to light. If now we coat a glass plate with collodion and then flow a moderately thick film of the bichromated gelatine thereon, and afterward expose this film to a strong light through a negative, the parts acted upon by the light become insoluble, and those parts protected from the light are easily soluble and capable of being washed out. After a suitable period this gelatine becomes so very hard that it is then possible to take an impression from it in soft metal. This is no discovery of mine; it is an old and much used idea.

To return to the electrical portion again. To transmit pictures electrically between, say, New York and Philadelphia, we arrange two machines, one at each end of the line and both working synchronously. This, it will at once be evident, is imperative.

We will suppose that we are sending from New York to Philadelphia. A revolving table A has mounted upon it a bichromated gelatine film treated as described above. This film is shown in cross section at B. It will be noted that the surface is irregular, corresponding in its elevations to the lights and darks of the picture. It is, in fact, a perfect picture in intaglio.

A tracing point C, mounted under the diaphragm D, works, or rather rests, lightly on the surface of the film. The diaphragm is supported at E E, and is connected to one pole of a galvanic battery. F is a platinum contact and G



Transmitting Pictures Electrically.

a carbon button. P P are the primary wires leading to the induction coil H.

The action will now be easily understood. The table A is slowly revolved, and the diaphragm D, with its tracing point C, is fed slowly from the outer edge toward the centre. The elevations and depressions of the picture cause the diaphragm to vibrate, and a greater or less current passes through the primary circuit to the induction coil, varying, of course, with the amplitude of vibration of the diaphragm, and its corresponding pressure of the carbon button G.

The secondary wires J J are led one to ground and the other to the distant station to the electro-magnet K. The varying impulses from the secondary acting through the magnet K causes the diaphragm L to repeat every movement of the transmitting instrument D.

In the receiving instrument we replace the tracing point with a lead pencil or other marking device, and stretch upon the table N a sheet of paper. The movements of the tables A and N are rotary and synchronous. The transverse motions of the tracer C and the lead pencil M are at the same speed; consequently, with each electrical impulse, we obtain at the receiving station a line either dark or light, as the vibration of the transmitting diaphragm has been great or small, and finally we finish with a perfectly shaded picture, an exact reproduction in chiaroscuro of the original photograph.

ELECTRIC CARS IN ROCHESTER, N. Y.

Electric cars have quickly made their way into popular favor in Rochester. The Rochester Railway Co. are running 12 electric cars on the Lake and South avenue lines, the power being furnished from the plant of the local Brush Electric Light Co. The receipts per day average 150 per cent. more than they did under the old horse car regime.

THE EICKEMEYER STREET RAILWAY MOTOR.

Our readers will recall the fact that during the summer of 1887 Mr. Stephen D. Field operated an electric locomotive on the 34th street branch of the elevated railroad in this city. The essential feature of this locomotive lay in the fact that the machine was designed with a very powerful torque, and that the armature was provided with a crank and geared direct to the drivers by a connecting rod. This was a decided departure in electric railway work and was watched with considerable interest by all concerned in the solution of the electric railway problem. The results obtained on that occasion convinced the designer of the correctness of his principle, and shortly afterwards a street car was constructed on an analogous principle, in which the well-known Eickemeyer motor was employed as the driving power. This car, constructed some two years ago, at Yonkers, was put in operation at Steinway, N. Y., and though not differing from the original design has operated to entire satisfaction.

Our engraving, Fig. 3, shows the car as it stands on the track. The Eickemeyer motor employed is geared direct to the drivers, which are 18 inches in diameter, the radius of the crank being 3 inches. The motor, which is capable of developing 25 h. p. at 300 volts, weighs about 2,400 pounds. The armature is 12 inches in diameter and 17½ inches long, and upon it are wound four layers of No. 9 B. & S. gauge, having 560 turns, equal to a resistance of .65 ohm. The field consists of 900 turns of No. 8 B. & S. wire, and is in series with the armature and by means of the switch can be grouped into various combinations of sections, either parallel or series, and when all in parallel has a resistance of .3 ohm. At 150 revolutions of the motor the car has a speed of 8½ miles an hour.

We have had occasion recently to inspect this road and to ride upon the car, and from actual experience can assert that in ease of starting and evenness of motion, the car leaves nothing to be desired. It was able to overcome quite a severe curve and grade with the greatest ease. It was also noteworthy that the momentary increase of current upon starting the car was but a very small fraction above that ordinarily required for propulsion, as the counter E. M. F. of the armature was immediately developed on account of the intense field.

Among the roads which will shortly be equipped with the Eickemeyer system is that at Lynchburg, Va., and the engravings, Figs. 2 and 1, show a side elevation and plan of the trucks which will be employed there. The motors are larger than the one just described and weigh 3,500 pounds. The diameter of the armature is 13¾ inches and its length 18½ inches. It is wound with three layers of No. 10 B. & S. wire, having 440 turns and a resistance of .7 ohm. The field is of No. 9 B. & S. wire and has a resistance of .6 ohm with all the coils in parallel. The motor, which is designed to develop 35 h. p. at 500 volts, will be geared

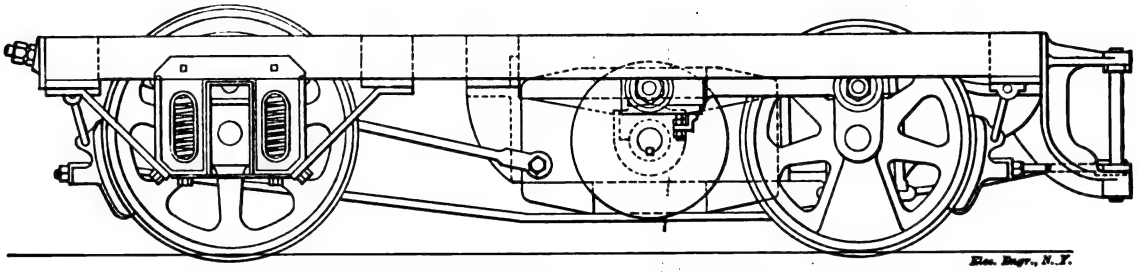


Fig. 2.—Eickemeyer Direct Geared Electric Railway Truck.

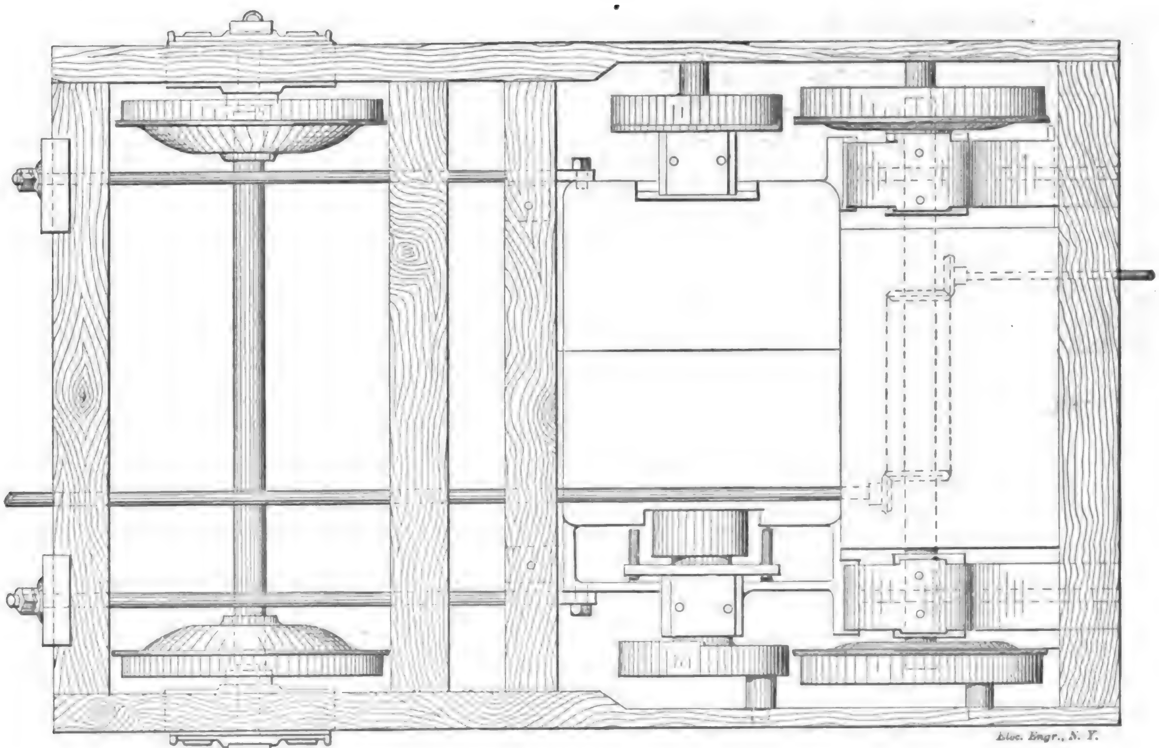

Fig. 1.—Eickemeyer Direct Geared Electric Railway Truck.

directly to the drivers by a five-inch crank, the drivers being 26 inches in diameter. Under these conditions a speed of 10 miles per hour will be attainable with only 120 revolutions per minute of the motor.

As in Mr. Eickemeyer's dynamos, these motors are all supplied with carbon brushes, but unlike the usual type of solid blocks, a multiplicity of contacts is obtained by securing a series of carbon buttons to a spring plate, which presses them against the commutator and thus provides a number of contacts for the path of the current. As before remarked, the momentary increase of current upon starting the car is exceedingly small in the Eickemeyer motors, which is largely due to the great density of field employed. Thus in the armature a density of no less than 110,000 lines per square inch is used. Preparations are now actively going forward and the Lynchburg road will shortly be put in operation, being equipped with Eickemeyer generators in the motive plant.

FIG. 3.—EICKEMEYER ELECTRIC STREET CAR.

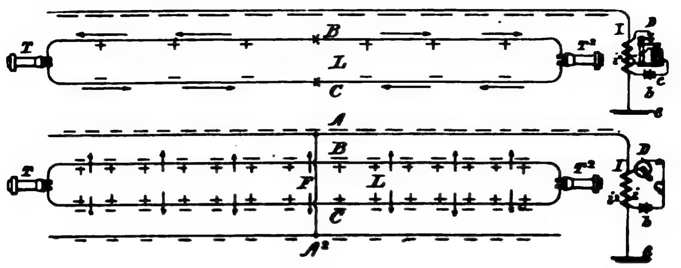
CARTY'S METHOD OF REDUCING INDUCTION IN TELEPHONE CIRCUITS.

IN a most interesting lecture delivered last winter before the New York Electric Club, Mr. J. J. Carty, electrician of the Metropolitan Telephone Co., of this city, showed how, besides the disturbances caused by dynamic induction between wire and wire, others of no less importance and effect were caused by static induction; and further, that while a circuit might be balanced dynamically with respect to a neighboring telephone circuit, if unbalanced statically, disturbances might be produced on the telephone circuit.

Let us suppose for instance that in the accompanying diagram A is the disturbing wire, which we will consider as being discontinuous at the outer end and as being at a given moment charged to a definite negative potential by the circuit breaker D, which interrupts the current of the battery in a local circuit, within which the primary helix of the induction coil I is included. The secondary helix I^2 of the induction-coil is in the line-circuit, and the entire apparatus may be regarded as the source of sound.

The negative charge on A of course tends to induce an equal positive charge, indicated by the plus-symbol on the line-wire B of the parallel metallic circuit L, and consequently a negative charge of like amount on the more distant linear conductor C of the same circuit.

Speaking conventionally, we may say that the electricity of the circuit L is decomposed, a positive charge being attracted to the side B nearest to the inducing charged wire, while a corresponding charge of negative sign is repelled



FIGS. 1 AND 2.—CARTY'S METHOD OF BALANCING TELEPHONE CIRCUITS ELECTROSTATICALLY.

to the more distant conducting-surface of C. This redistribution results, of course, in currents through telephones T and T^2, producing noise corresponding to the note given out by the circuit breaker, and if the disturbing-line A were engaged in telephonic transmission the telephones T and T^2 would reproduce the speech transmitted over A.

To prevent this inductive interference therefore, Mr. Carty has designed and patented the arrangement of circuits shown in Fig. 2. The metallic telephone-circuit L is identical with that shown in Fig. 1, the telephone T being included therein at one end and the telephone T^2 at the other. The disturbing conductor A, having an earth terminal *e* and provided with the induction coil I, through which vibratory impulses are thrown on to the line tending to produce a musical note and actually establishing thereon, as long as the line is open, a varying potential, is now provided with an associate line-conductor A^2, holding the same inductive relation to the conductor C of the metallic circuit L as does A to the conductor B; that is, the wire A^2 is run parallel to, and for the same length as, C and at the same distance therefrom as A is from B. A cross-wire or connecting-conductor F, located at any suitable point of the line, unites A and A^2. When these are joined, as shown, the disturbing wire being operative, no sound is heard either at T or T^2.

This is readily explained by a consideration of the conditions, for A^2 being at all times at the same potential as A, acts with the same force as C that A does on B, and while A does, indeed, tend at any given moment to attract a

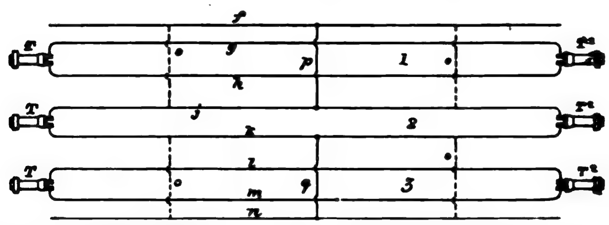


FIG. 3.—CARTY'S METHOD OF BALANCING TELEPHONE CIRCUITS ELECTROSTATICALLY.

positive charge on B and to repel an equal and opposite charge to C, it is also true that its associate conductor A^2, electrified at the same moment to the same potential, tends to attract a positive charge to C and to repel an equal and opposite charge to B. The resultant effect is, of course, zero, or neutrality, or, as indicated by the arrows, the flow or rearrangement of the charge will be lateral and the telephone T and T^2 will be silent.

The diagram, Fig, 3, shows one manner in which the principles just pointed out can be practically applied three metallic circuits being shown. By this arrangement the circuits 1, 2 and 3 are freed from disturbance due

to electrostatic induction. The action of the compensating wires f and n is like that of a condenser, each wire acting as one plate.

It will be apparent, therefore, that they may be replaced by a series of condensers distributed along the line, their total capacity equaling the capacity of the compensating wire which they replace.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—VI.

(*Copyright, The Electrical Engineer.*)

BY HERBERT LAWS WEBB.

BRIDGES.

The Post-office form of bridge, illustrated in Fig. 22, is smaller and more compact than the dial pattern and is therefore more suitable for out-door work than for laboratory use. Its range is more limited as the proportional coils only contain three different resistances, 10, 100 and 1,000 ohms, instead of four; it can, therefore, only measure from .01 of an ohm to 1 megohm.

The adjustable coils are sixteen in number, their values being 4, 3, 2, and 1 in thousands, hundreds, tens and units, giving any combination up to 9,999 ohms. The coils are thrown in circuit by taking out plugs instead of putting them in, as in the dial bridge, and the resistance measured is ascertained by adding up the values of the various coils unplugged, which is not quite such a simple operation as reading off a figure from each of four dials. The two small keys fixed in front of the coils serve, the one on the right, for putting on the battery, and that on the left, for throwing the galvanometer in circuit. The right hand key is generally held down and the left tapped from time to time as the plugs are manipulated; in this way sudden throws of the galvanometer are avoided, the left hand key not being kept down for any length of time until an even balance is nearly obtained. A small clamp for holding the battery key down permanently would be a useful addition to a Post-office bridge, as the two hands of the observer would then be free for manipulating the plugs and the galvanometer key.

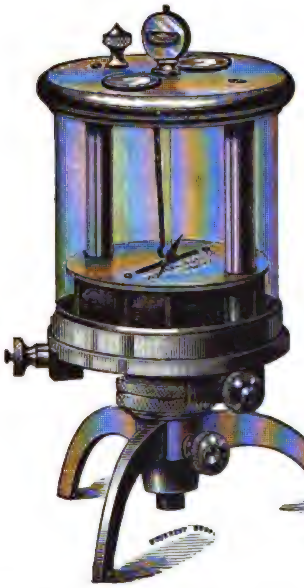

FIG. 23.—SMALL ASTATIC GALVANOMETER.

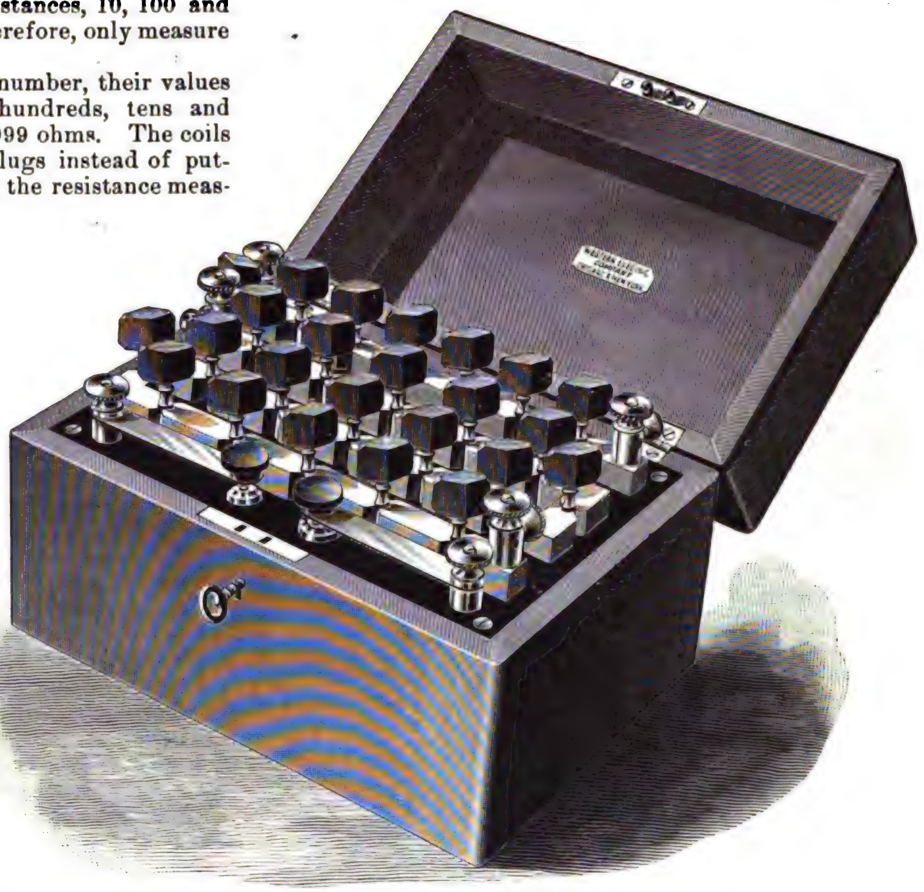

FIG. 22.—WHEATSTONE BRIDGE, POST OFFICE FORM.

The small astatic detector galvanometer, illustrated in Fig. 23, is an excellent little instrument for work-shop or factory use with a Post-office bridge. Its small size renders it available for portable work and it can be set up quickly and in places where a reflecting galvanometer would be out of the question, while it is sufficiently sensitive for ordinary resistance measurements.

A box containing adjustable resistance coils from 1 to 1,000 ohms is a useful adjunct to a set of testing instruments. As an instance of its usefulness, reference is only needed to the labor of working out the multiplying value of shunts of different resistances, whenever a shunt is required to a different value from any of the three unadjustable coils supplied with the galvanometer. Of course the resistance of a galvanometer varies considerably with the temperature, and a table of shunt resistances and multiplying values would be incorrect except at the temperature at which the resistance of the galvanometer was exactly that used in calculating the table. By connecting an adjustable resistance in circuit with the galvanometer the variation in resistance due to temperature may be made up and the resistance of the galvanometer kept always practically the same. In this way a table of shunts can be made out, giving the multiplying value for various resistances, using the formula given before, $\frac{G+S}{S}$. This arrangement, facilitating the use of shunts of various values, will be found very useful in factories where numbers of cables and wires have to be tested daily; the chief advantage being that the galvanometer can be shunted so as to give any desired deflection, large deflections, of course, being read with greater ease and accuracy than very small ones.

CONDENSERS.

The simplest method of measuring the electrostatic capacity of a wire or cable, is, as has already been stated, by comparing the charge or discharge with the charge or discharge of a standard condenser. A condenser is simply a Leyden jar arranged so as to occupy the smallest possible

space; the condensers used in telegraphy and telephony consist of leaves of tin foil separated by leaves of paraffined paper. In making condensers for standards for testing purposes a finer degree of adjustment is necessary and plates of mica are generally used for the insulating medium, instead of paraffined paper.

In the Leyden jar one surface of tin foil is connected to ground and the other to the source of electricity by means of which it is charged, the glass bottle serving as the separating medium or dielectric. In order to obtain a large charging surface the alternate plates of tin foil in a condenser are connected together, thus forming two large plates made up of a number of small ones, much as a number of cells of battery, connected in parallel, practically form one cell having very large plates. Each set of plates is connected to a brass block on the top of the case; when the condenser is in use one of these blocks is connected to earth and the other to the charging key.

The unit of capacity is the "farad." A condenser which would hold a charge of one coulomb at a differeuce of potential between the plates of one volt would have a capacity of one farad. Such a condenser would be of enormous size, and the farad is such an inconveniently large unit that it has been necessary to divide it by one million to arrive at a unit of reasonable proportions; consequently measurements of capacity are always expressed in microfarads or fractions thereof. Standard condensers were first made for submarine cable testing, and as the capacity of a submarine cable is about one-third of a microfarad per mile the standards were always made of that capacity for convenience in comparison.

For general work, however, a non-adjustable condenser is not at all a convenient instrument to deal with, as it is highly necessary to be able to vary the capacity of the condenser, using one-tenth, or one-fifth, or some other fraction of a microfarad, instead of always one-third. Until lately adjustable condensers have had one serious defect, namely, that the different sections could only be connected in parallel, instead of being arranged so as to be connected both in parallel and in series. Standard condensers are now made, however, so arranged that the various sections may be connected either in multiple or series, or the sections may be used as separate condensers if desired.

To appreciate the advantage of having a condenser arranged in this manner it is necessary to discuss briefly the laws governing the joint capacity of condensers connected in parallel and in series. These laws run on parallel lines to those referring to the joint resistance of divided circuits, but with condensers exactly opposite results are obtained, as by connecting them in parallel the capacity is increased, and by connecting them in series the capacity is diminished; with resistances the effect is reversed. Connecting in series increases the resistance and connecting in parallel or in "multiple arc" diminishes it.

If we have a number of condensers joined in parallel the joint capacity will be equal to the sum of their respective capacities. When we connect them in series a very different result is obtained; their joint capacity is then only a fraction of the capacity of a single condenser. When condensers are joined in series their joint capacity is determined by the same law that governs the joint resistance of parallel circuits. The joint resistance of two wires joined in parallel circuit is equal to their product divided by their sum, thus: $\frac{R_1\ R_2}{R_1 + R_2}$ ohms,

and the joint capacity of two condensers joined in series is expressed in the same manner:

$$\frac{F_1\ F_2}{F_1 + F_2} \text{ microfarads.}$$

If we have three condensers in series the joint capacity is

$$\frac{F_1\ F_2\ F_3}{F_1\ F_2 + F_1\ F_3 + F_2\ F_3}.$$

The joint capacity of any number of condensers connected in series may be arrived at in the same manner, or in simpler form it may be written thus:

$$\frac{1}{\frac{1}{F_1} + \frac{1}{F_2} + \frac{1}{F_3} + \frac{1}{F_4}, \text{ etc.}}$$

Putting this expression into words, it is evident that the joint capacity of a number of condensers joined in series is equal to the reciprocal of the sum of the reciprocals of their respective capacities.

Thus if we have a condenser having ten sections of a capacity of one-tenth of a microfarad each, the joint capacity of the ten sections connected in parallel will be one microfarad, and if one side of each section is permanently connected to the earth block the range of the condenser will be confined between one-tenth and one microfarad. If, however, the plates of each section are connected to insulated blocks so that the sections may be disconnected from the earth block and connected together in series, then the range of the condenser will be greatly increased as far as small fractions of a microfarad are concerned. If we connect the whole ten sections in series, the rule of "the reciprocal of the sum of the reciprocals" shows that the joint capacity will be .01 microfarad; therefore a condenser arranged in this manner has a range of capacities from .01 to 1 microfarad.

VARIATIONS IN THE E. M. F. OF CELLS.[1]

The description of the apparatus, the capillary electrometer, and method of working are given fully in the paper. The following conclusions are drawn from the results of the experiments:

I. When the metals, copper, silver, bismuth and mercury, are introduced into purified nitric acid of different degrees of concentration, and a couple made with platinum, the E. M. F. of such a cell increases considerably from an initial point until it reaches a constant and in most cases a maximum value. The rise of E. M. F. is attributed to the production of nitrous acid by the decomposition of the nitric acid, and the final value is considered to be due to the former acid only, while the initial value is due for the most part to the latter acid, though it is affected to a remarkable degree by the amount of impurity of nitrous acid, either initially present or produced by minute and unavoidable uncleanliness of the metallic strip and the containing vessel.

II. If nitrous acid has been previously added to the nitric acid, then the maximum E. M. F. is reached at once.

III. If the conditions—namely, increase of temperature, of impurity, and of concentration of acid—are such as would favor a more rapid solution of the metal, and consequently a more rapid production of nitrous acid, then the rise of E. M. F. is concomitantly more rapid.

IV. Conversely, if the conditions are unfavorable to the production of nitrous acid, the rise of E. M. F. is less rapid.

V. If any substance, such as urea, be added which would tend to destroy the nitrous acid as fast as it may be formed, then the rise of E. M. F. is extremely slow, being dependent upon the number of molecular impacts of the nitrous acid upon the surface of the metal. Thus, the results obtained by the electrometer are confirmatory of those obtained by the latter author with the chemical balance.

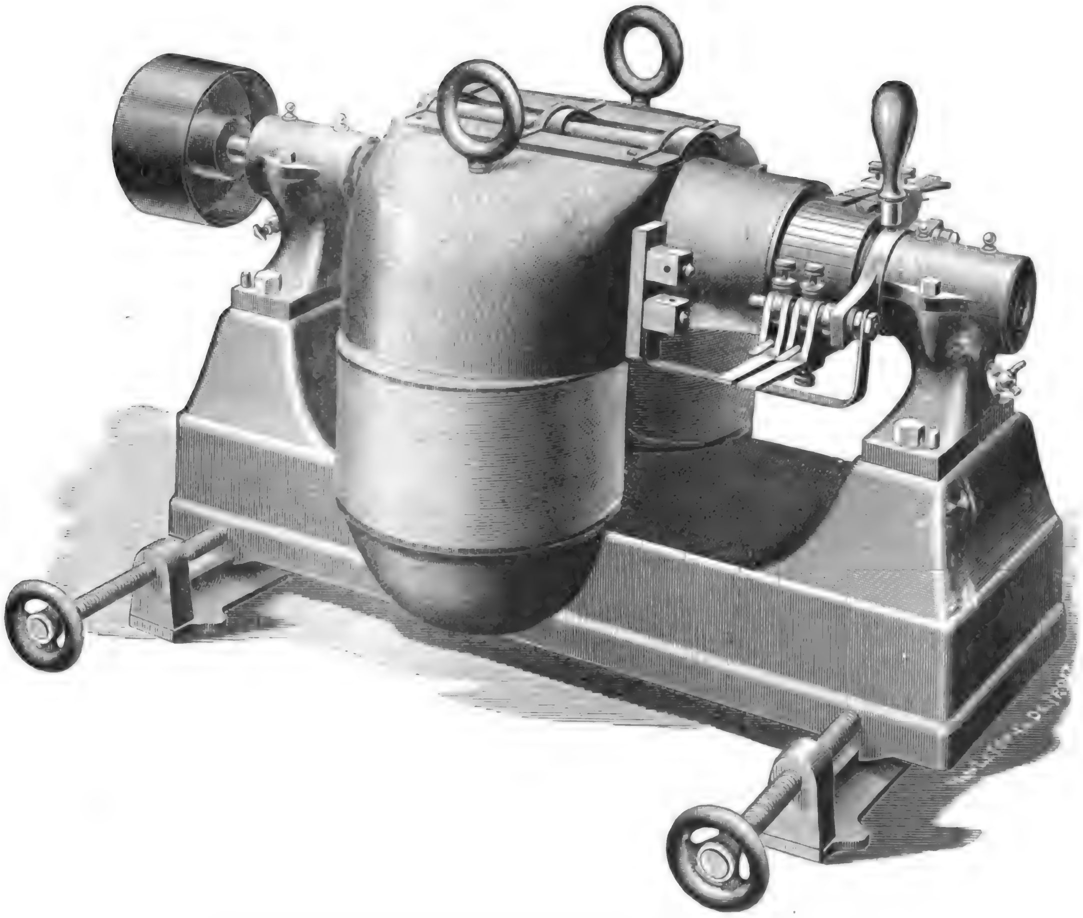
The authors propose to carry on further investigations on kindred problems.

[1] Abstract of a paper on "The Variations of E. M. F. of Cells, consisting of certain Metals, Platinum and Nitric Acid," read by Messrs. G. J. Burch and V. H. Veley, University Museum, Oxford, before the Royal Society, Nov. 27th, 1890.

THE BLADES DYNAMO.

The accompanying engraving illustrates the new dynamo designed by Mr. H. H. Blades, electrician of Detroit Electric Motor Co., in which attention has been devoted equally to the mechanical and electrical features.

The machine was designed to take advantage of the many good points of the single circuit, horse-shoe type of magnet and at the same time to eliminate and lessen some of the undesirable features of that type. It has been common in such machines to have a zinc or wood base interposed below the armature for the purpose of partially preventing short-circuiting of the magnetism. In the usual form of the inverted type, the moving parts, the armature and shaft, have been high above the centre of gravity; and in some, where the shaft is lower, cast-iron magnet cores of an oblong shape have been resorted to. In this machine it has been the purpose to avoid these features and at the same time to make the machine electrically and mechanically correct.



The Blades Dynamo of The Detroit Electric Motor Co.

The dynamo will be manufactured in 18 sizes, from one of 1,100 watts to one with a capacity of 160,000 watts, the patterns for all of which are finished. The 80,000 watt machine weighs 13,000 pounds and gives 145 amperes at 550 volts, running at a speed of 480 revolutions per minute. The magnetizing current at 550 volts is 1.2 ampere. The armature core of the 100 h.p. machine is 12 inches in diameter and 26 inches long. It is made up of about 850 charcoal iron discs, separated by paper, the oxide having first been removed from the surface of the iron. The magnet cores are of the softest forged iron.

A feature of the mechanical construction consists in a clearance hole bored through the centre of each magnet core. Through this hole passes a long bolt which screws into the bottom of the pole-piece, and the other end of the bolt is fastened with a nut under the yoke-bed, dowel-pins being employed to hold the parts in place. In this way the parts are more easily made interchangeable. The pole-pieces are bored on a form, the central points of which correspond with those on the bed-frame, making the matter of assembling an easy one.

THE RUMFORD MEDAL FOR HERTZ.

At the anniversary meeting of the Royal Society, held recently, the Rumford medal was presented to Prof. Heinrich Hertz, for his work in electro-magnetic radiation, and a Royal medal to Dr. J. Hopkinson, for his researches in magnetism and electricity. The society elected the officers and council for the ensuing year, and Sir William Thomson was chosen president in succession to Sir G. Stokes. In the evening Sir W. Thomson took the chair, as president, at the dinner of the Society at the Hôtel Métropole.

A PITHY PLEA FOR THE POLES.

The new poles for the incandescent light, which are now being put up in all parts of town, give evidence, says the Albuquerque, N. M., *Citizen*, that this new and improved electric light will soon be here. The new poles, in addition to those of the telegraph company, the arc light and the telephones, which are already here, make some of our streets regular forests of poles. Well, it looks like "business," and we shan't agitate the idea of putting the wires underground—at least not right away. Telegraph poles and railway tracks may cause some inconvenience when they become too numerous, but they constitute a compound nuisance which we have no disposition to abate. Let them multiply. Poles and tracks don't come where there is no business for them, and their presence here is the best evidence we can give to the public that the business of the town demands them.

MR. BRUSH'S WINDMILL ACCUMULATOR PLANT.[1]

The mill here shown, as well as all of the electrical apparatus used in connection with it, and the very complete system by which the results are secured, have been designed and carried out according to the plans of Mr. Charles F. Brush, of Cleveland, Ohio, and under his own personal supervision. As an example of thoroughgoing engineering work it cannot be excelled.

Every contingency is provided for, and the apparatus, from the huge wheel down to the current regulator, is entirely automatic.

The reader must not suppose that electric lighting by means of power supplied in this way is cheap because the wind costs nothing. On the contrary, the cost of the plant is so great as to more than offset the cheapness of the motive power. However, there is a great satisfaction in making use of one of nature's most unruly motive agents.

Passing along Euclid avenue in the beautiful city of Cleveland, one will notice the magnificent residence of Mr. Brush, behind which and some distance down the park may be seen, mounted high on a tower, the immense wheel which drives the electric plant to which we have referred. The tower is rectangular in form and about 60 feet high. It is mounted on a wrought iron gudgeon 14 inches in diameter and which extends 8 feet into the solid masonry below the ground level. The gudgeon projects 12 feet above the ground and enters boxes in the iron frame of the tower, the weight of the tower, which is 80,000 pounds, being borne by a step resting on the top of the gudgeon. The step is secured to a heavy spider fastened to the lower part of the frame of the tower.

In the upper part of the tower is journaled the main wheel shaft. This shaft is 20 feet long and 6½ inches in diameter. It is provided with self-oiling boxes 26 inches long, and carries the main pulley, which has a diameter of 8 feet and a face of 32 inches. The wheel, which is 56 feet in diameter, is secured to the shaft and is provided with 144 blades, which are twisted like those of screw propellers. The sail surface of the wheel is about 1,800 square feet, the length of the tail which turns the wheel toward the wind is 60 feet, and its width is 20 feet. The mill is made automatic by an auxiliary vane extending from one side, and serving to turn the wheel edgewise to the wind during a heavy gale. The tail may be folded against the tower parallel with the wheel, so as to present the edge of the wheel to the wind when the machinery is not in use. The countershaft arranged below the wheel shaft is 3½ inches in diameter, it carries a pulley 16 inches in diameter, with a face of 32 inches, which receives the main belt from the 8-foot pulley on the wheel shaft. This is a double belt 32 inches wide. The countershaft is provided with two driving pulleys each 6 feet in diameter, with a face of 6½ inches, and the dynamo is furnished on opposite ends of the armature shaft with pulleys which receive belts from the drive wheels on the countershaft.

The dynamo, which is one of Mr. Brush's own design, is mounted on a vertically sliding support and partially counterbalanced by a weighted lever. It will be seen that the countershaft is suspended from the main shaft by the main belt, and the dynamo is partly suspended from the countershaft by the driving belts. In this way the proper tension of the belts is always secured, the total load on the dynamo belts being 1,200 pounds, and on the main belt 4,200 pounds. The ends of the countershaft are journaled in sliding boxes connected by equalizing levers which cause both ends of the shaft to move alike. The pulleys are so proportioned that the dynamo makes fifty revolutions to one of the wheel. The speed of the dynamo at full load is 500 revolutions per minute, and its normal capacity at full load is 12,000 watts.

The automatic switching devices are arranged so that the dynamo goes into effective action at 330 revolutions a minute, and an automatic regulator is provided which does not permit the electromotive force to run above 90 volts at any speed. The working circuit is arranged to automatically close at 75 volts and open at 70 volts. The brushes on the dynamo are rocked automatically as the load changes. The field of the dynamo is slightly compounded. The current passes from the dynamo to contact shoes of polished and hardened steel carried by a cross bar on the tower, which shoes slide on annular plates surrounding the gudgeon. Conductors extend underground from these plates to the dwelling house. To guard against extraordinary wind pressure, the tower is provided at each of its corners with an arm projecting downwardly and outwardly, and carrying a caster wheel very near, but not in contact with, the circular rail concentric with the gudgeon. Ordinarily, these caster wheels do not touch the rail, but when the wind is very high, they come into contact with the rail and relieve the gudgeon from further strain.

In the basement of Mr. Brush's house there are 408 secondary battery cells arranged in twelve batteries of 34 cells each; these 12 batteries are charged and discharged in parallel; each cell has a capacity of 100 ampere hours. The jars which contain the elements of the battery are of glass, and each cell has its liquid covered with a layer of "mineral seal" oil, a quarter of an inch thick, which entirely prevents evaporation and spraying, and suppresses all odor. The automatic regulating devices are shown in one of the views of our engraving. At 1 are shown the voltmeters and ammeters employed in measuring the charging and discharging currents; at 2 is shown a series of indicators, one for each battery; 3 represents an electrically operated switch by means of which the current may be turned on or off the house mains by pressing push buttons in different portions of the house; 4 represents a ground detector, which is connected with the centre of the battery and with the ground, so that should the conductor upon either end of the battery be grounded, the fact will be indicated by the movement of the index in one direction or the other from the zero point of the scale, thus showing not only that the battery is grounded, but indicating the grounded pole; 5 is a leakage detector connected up with the lamp circuits, and arranged to show any leakage from one conductor to the other; at 6 is shown a compound relay for operating the automatic resistance shown at 7. This resistance is placed between the batteries and the house mains, and is arranged to keep the voltage on the lamps constant at all times. In this device the resistance is secured by means of powdered carbon placed under varying pressure, the necessary movement being made by means of hydraulic pressure under the control of the relays.

The house is furnished with 350 incandescent lights, varying from 10 to 50 candle power each. The lamps most commonly used are from 16 to 20 candle power; about 100 incandescent lights are in every day use. In addition to these lights there are two arc lights and three electric motors. It is found after continued use of this electric plant that the amount of attention required to keep it in working condition is practically nothing. It has been in constant operation more than two years, and has proved in every respect a complete success.

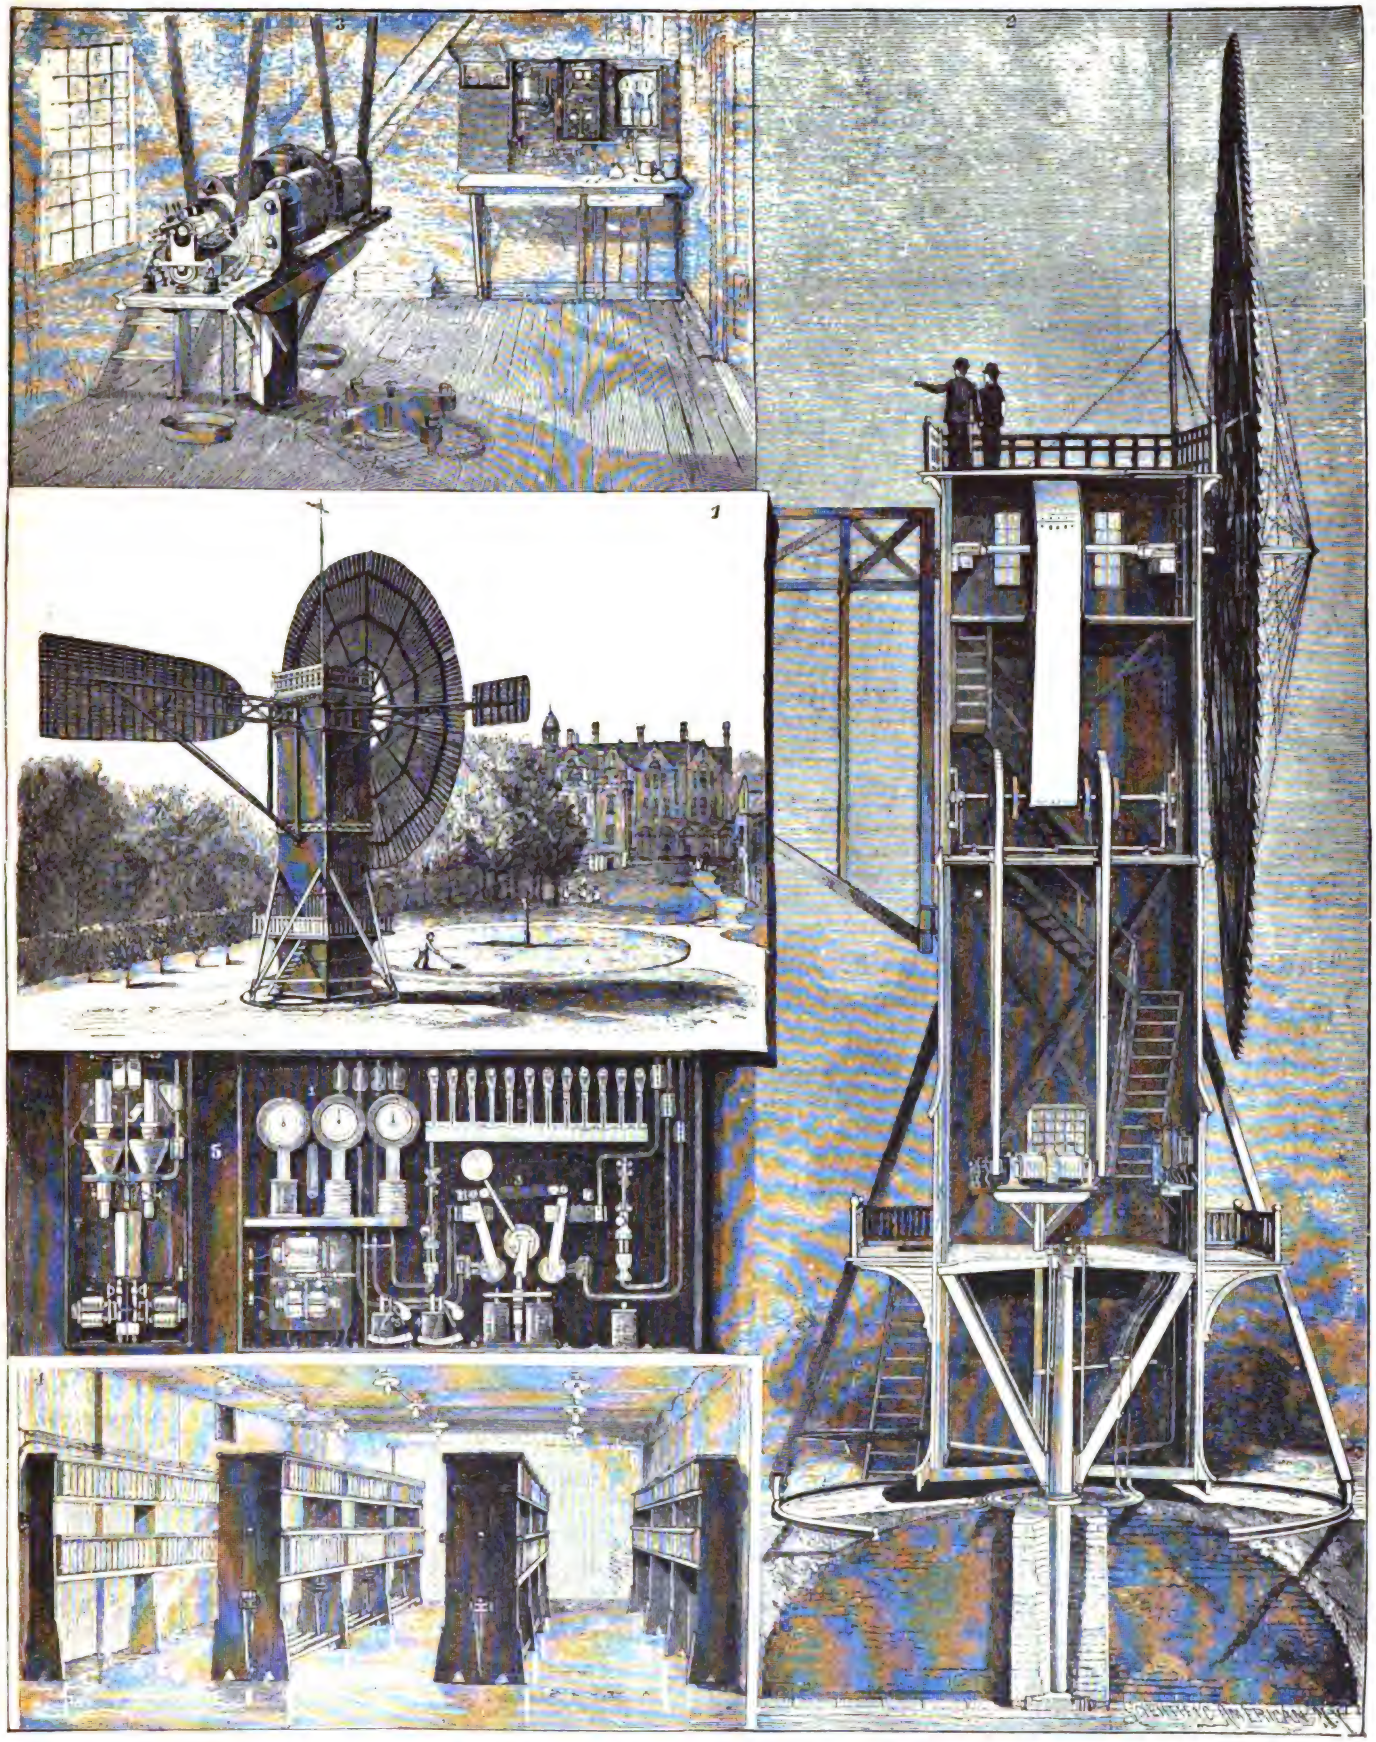
1. *Scientific American.*

THE ELECTRIC LIGHT AS A PROTECTION TO WOMEN.

The city council, of Appleton, Wis., has passed a resolution to the effect that the city in future must be lighted with electricity in place of gas, which is used at present, owing to the fact that so many women are insulted nightly on account of the poorly lighted streets. The city was also authorized to borrow $43,000 with which to carry on the improvements.

POSTAL TELEGRAPHS.

A special dispatch from Washington of December 16 says that the House Committee on Post Offices has resolved to report to the House a resolution setting apart January 6 for the consideration of the Postal Telegraph bill.



WINDMILL AND STORAGE BATTERY ELECTRIC LIGHT AND POWER PLANT OF MR. CHARLES F. BRUSH, AT HIS RESIDENCE, CLEVELAND, O.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. X. NEW YORK, DECEMBER 24, 1890. No. 188

Over one hundred men, of the highest ability as original investigators, have toiled an average of ten years each, at the problems of magnetism, thus making an aggregate of one thousand years of successful search in this rich mine of natural truth.—Alfred M. Mayer.

THE HENRY AS THE UNIT OF INDUCTANCE.

IT has often been remarked that modern science is becoming overburdened with units and that in the department of electricity especially this tendency is being carried almost to excess. We think, however, that no one who ponders upon the importance of well established standards and the frequency with which they are used in actual practice as well as in theoretical discussions, can deny their great utility, and, indeed, absolute necessity. The great advances which have been made in alternate current machinery and the studies which are based upon them have long made it desirable to establish a unit of inductance. This was done at the late Paris Congress, but the name selected for the unit, the quadrant, not being in conformity with the general designation of electrical units in which the names of great electricians have been employed, the Henry was very properly suggested and endorsed by the American Institute of Electrical Engineers, and has indeed already been introduced and familiarized by writers on the subject. Having determined upon the adoption of a name it now becomes necessary to establish the value of the working unit, and here, as will readily be seen, a diversity of opinion is liable to occur. The absolute value of the unit of inductance is well determined and defined and can of course not be altered, but in view of the large range of inductance found in apparatus existing in actual practice, there is a question as to the value to be assigned to the most convenient working unit of inductance. The subject has been presented in a masterly manner by Mr. Kennelly in his paper read before the Institute of Electrical Engineers in which he gives a résumé of the history of the unit and to which he adds a large number of examples upon which the selection of a working unit may be based. Mr. Kennelly, it will be noted, inclines to the belief that the thousandth of the earth quadrant or henry would be the most eligible, as being nearest the mean of the values generally found in practice. Whether this value as the working unit be adopted, or not, seems to us of lesser importance than the preservation of the term henry as the unit which is directly related to and derived from the other established units. We may in fact distinguish three classes of units: First, the absolute unit; second, the practical unit; and third, the working unit. In several cases the absolute and practical units now existing coincide in value, but in others they differ and we think that in the case of the henry the same rule ought to be followed that has heretofore been pursued, so that the interdependence of the unit system will remain unbroken and the term henry will always be directly related to the other units. Lapse of time may dictate, as has recently been proposed in the case of the ampere, a change in the value of the working unit, so that if designated by the term, henry, considerable difficulty would be experienced in its adoption, not to speak of the confusion which an old unit and a new unit designated by the same term would bring about. Mr. Kennelly has so clearly stated the case that the discussion which is to follow shortly will, we hope, be as thorough as the present situation permits.

ELECTRO-DEPOSITION OF COPPER.

IN our issue of Nov. 12 we pointed out several errors into which our esteemed contemporary, the London *Electrical Review*, had fallen in its discussion of the economy of the electro-deposition of copper. The points to which we drew attention related solely to matters of practice and of record. As a reply to the errors pointed out by us, our contemporary now refers us to a letter by one of its correspondents, Mr. Desmond G. Fitz-Gerald, which we are told will have the effect of "moderating our transports." We have carefully read Mr. Fitz-Gerald's letter a number of times, but fail to find anything in it controverting the points made by us. That Mr. Fitz-Gerald has thoroughly understood the position taken by us is evident from the fact that he devotes seventeen lines to a categorical statement of the same and then needs nearly two columns to prove that identically the same amount of copper is deposited whether there be employed a current of a large number of amperes at low voltage, or a smaller current at a correspondingly higher voltage. Mr. Fitz-Gerald might have spared himself this trouble, as we fully agree with him on this point, which, indeed, is so obvious that it should require no special or longwinded explanation at this late day. What this has to do with the subject under discussion, however, we fail to see, and hence, if this be our contemporary's reply to our criticisms we must be allowed to consider them as still unanswered. The reference by our contemporary to the similarity of Mr. Stepney Rawson's criticisms to those contained in our editorial remarks we may pass over as beneath notice, unless a pleasantry be intended. If so, we fail to see the joke.

THE POSTAL TELEGRAPH "MOVEMENT."

The movement to place the telegraphs of the country under government control is but another form of the agitation that is intended to place in the hands of municipal bodies the ownership of gas and electric light plants, street car lines, water works and other necessities or conveniences. It is with a recognition of this fact, evidently, that Mr. M. J. Francisco, of the National Electric Light Association, has made an argument at Washington, before the Post Office Committee of the House, in reply to the argument of Postmaster-General Wanamaker favoring a limited postal telegraph service. A copy of Mr. Francisco's address has come into our possession, and we can but congratulate him on the able and effective plea he has made for freedom of private enterprise, basing his argument as he does on fundamental reasons for a broad, comprehensive and clear-cut policy that shall declare itself opposed to government ownership of any undertaking that is essentially commercial in its nature.

Unless we printed the whole of Mr. Francisco's argument, it would be impossible to give all the points he makes against Mr. Wanamaker, they are so numerous and so good, but reference to one or two is in order. Thus, for example, the Postmaster-General has claimed for his "limited" scheme the "strong endorsement of the press of the country." Well, out of 289 articles brought to his notice, no fewer than 209 are for postal telegraphy and 80 are against it! But as Mr. Francisco shows, a great many of the articles are not editorial expressions at all, but are frequently reports, correspondence, or copies of other articles. And then, to delude onesself into the notion that 209 such articles in 144 papers, many of them utterly obscure, represent the "strong endorsement" of the American press!

Mr. Wanamaker stated also that he had received, without any effort on his part, memorials of some twenty-five or thirty boards of trade or chambers of commerce supporting the limited plan. But, as Mr. Francisco shows, this resulted wholly from the work of the New York Board of Trade and Transportation, and, as a matter of fact, the model resolution sent out for adoption was not for the "limited" plan but a committal to the plan of outright government ownership. Here again the paucity of numbers is really striking. This handful of organizations does not represent the sound judgment of the business communities of America. It may be asserted beyond all doubt or fear of contradiction, that the vast majority of the 900 boards of trade and chambers of commerce have not supported the limited plan and would not favor it as a "first step in the right direction" of spending $150,000,000 in the purchase of the telegraphs and telephones of the country.

Mr. Francisco also does a service in bringing forward the utterances of postmasters general who have pronounced against government telegraphs, and in demonstrating how feebly after all the "will of the people has been manifested before Congress in public speech and statement during the last twenty years." The talk about the popular will is absurd. Postal telegraphs are the very last thing one hears talked about by the people.

There has been a little disposition of late years toward the extension of State agency by enthusiastic theoretic people acting, as Herbert Spencer says, "on the tacit assumption that a government moulded by themselves has some efficiency beyond that naturally possessed by a certain group of citizens subsidized by the rest of the citizens," and to which they ascribe marvelous powers for doing multitudinous things quite beyond the reach of the ordinary, unofficial mortal. But, fortunately, there is still, on the other side, a robust belief that officialism is best when at a minimum. The truth is that anything done by the Government is apt to be done more badly and more slowly than if it were done by private individuals directly interested to secure success. Telegraphs would be no exception to the rule. And looking at the wider range of the same principles, applying as they do to electric light plants and electric railways, we are heartily with Mr. Francisco in his campaign against the scheme of the Postmaster-General.

MAGNETO-OPTICAL CURRENTS.

The correlation of the forces of nature is now so well established that the recent note of Prof. Sheldon on the magneto-optic generation of current, effected by reversing Faraday's experiment on the rotation of a beam of polarized light by the current, might well have been accepted as the result of legitimate a priori reasoning sustained by experiment. We must, therefore, confess to some surprise at the negative results obtained and reported in our columns this week by Prof. C. F. Brackett and Mr. S. T. Dodd. It is true that they point out the defects in the methods employed by Prof. Sheldon, due to the presence of electric currents whose influence masked the effects sought for, but we were hardly prepared to learn that their results, when the lime light was employed, were entirely negative. Granting the correctness of the results, one cannot help thinking that *some* effect is produced, but that even our most delicate instruments are not sufficiently sensitive to indicate, let alone measure, it. It is to be hoped that the question here involved will be made the subject of further study and research so that some definite conclusions may be reached.

The Voltmeter as a Testing Instrument.

The drop-in-potential method of testing is so simple that it has become the favorite one in the laboratory for many kinds of electrical testing, but the delicacy required in instruments to ensure accuracy has heretofore largely debarred this excellent method from use in the factory and central station. The Weston voltmeter, which has deservedly won a high reputation for accuracy, makes it possible, however, to perform a number of tests with an accuracy sufficient for all practical purposes and with the most simple auxiliary apparatus, and our readers will therefore be interested in the article by Mr. Osborn P. Loomis, which describes the use of the voltmeter in a number of tests of almost daily occurrence in the workshop and station. For those to whom the use of the reflecting galvanometer presents difficulties, the methods described by Mr. Loomis will prove of much benefit, the great portability of the instrument making it of additional value in out-door work.

INDUCTANCE AND ITS PROPOSED UNIT THE HENRY.[1]

BY A. E. KENNELLY.

PERHAPS the greatest discovery of Faraday's long career of scientific research was that of electro-magnetic induction in the year 1831, when he first brought to light the influence exerted by a magnet or a current upon surrounding matter when subjected to a change of magnetic potential. Oersted had shown that a conductor carrying a current exercised electro-magnetic influence at a distance, and Ampere had ennunciated those simple and beautiful laws this influence is admitted to obey, but Faraday's discovery was a great step; it revealed the action of magnetic force in apparently empty space; it inaugurated that deeper insight into the mechanism, still only dimly guessed, which connects matter with all other matter in space; and it invested the all pervading ether with a dignity and power that in the hands of many great men since his time has probably paved the way for our future comprehension of magnetism, gravitation, and radiant energy, while making the hypothesis of action-at-a-distance a mere mathematical conception and process of thought.

The development of this discovery of electro-magnetic induction has practically created electrical engineering, for it is to machinery operating by electro-magnetic induction that we owe nearly every branch of electrical industry except, perhaps, telegraphy, the forerunner of all; and the condition of modern electrical engineering is such that the units and nomenclature relating to steady currents and permanent magnets is insufficient for practical requirements, and the conditions developed by variable currents and magnets demand the establishment of engineering practical units for the purposes of convenience in expression and computation.

Foremost among these required units is that of inductance, or as it is commonly called the co-efficient of induction. This inductance is a property fully as essential to every electric conducting circuit as resistance and electro-static capacity, and the inductance of a circuit when conveying variable currents is often a far more important factor in regulating the flow than the ohmic resistance. In fact we know that Ohm's law does not apply to a circuit so long as the current is unsteady, unless the inductance of the circuit or the counter electro-motive force it involves be introduced into the expression.

In conformity with the conventional and so-called absolute units of electro-magnetism, an inductance is a length and theoretically can always be computed from the geometrical relations of a circuit; that is to say, if the distance of each point from all other points of a circuit be measured, or inferred, in inches or centimetres, the inductance of the circuit will be some definite number of inches or centimetres, capable of being determined by a possible if not a convenient process of summation. If the circuit, however, be associated with iron or other magnetizable matter, then the magnetic permeability of the environment will enter the terms of summation as a multiplier. In the absolute centimetre-gramme-second system of units, inductance will be necessarily expressed in centimetres, and the centimetre is thus the natural scientific unit, although unsuited to the requirements of electrical engineering.

It may be well to notice that inductance is only conventionally and perhaps not essentially a length. Professor Rücker has pointed out [2]that the multiplication of the permeability factor with the length factor is always tacitly, if not expressly involved, even when the circuit considered is far from magnetizable matter in the ordinary sense; that is to say when residing in a medium of unit permeability, and therefore the nature of inductance is not merely length, but length multiplied by permeability, while physics has not yet decided whether permeability is the simple numerical factor at present assumed, or a function of length, mass and time. Until this question is settled, the real nature of inductance must be considered as doubtful, and the fact that inductance will probably, in any event, be always measured by lengths is no more validly an argument as to its nature, than the usual determination of a body's mass by the earth's gravitational force upon it is an argument that mass is a force. However, the question is one of theory only, and does not affect the consideration of the practical unit.

As has been pointed out by Dr. Sumpner, [3]there are no less than three ways of defining the inductance of a circuit, or a portion of a circuit, and the three definitions are equivalent when the permeability of the magnetic medium is unity, but are not generally equivalent in the opposite event, being then only related in a definite manner by the magnetic properties of the medium. In other words, the inductance of a hollow solenoid of copper wire, placed in a vacuum and far from all iron, has the same numerical value in each of the three definitions, but if an iron core be inserted in it, its inductance will depend upon the definitions elected, and will only be capable of interpretation from its value in one to its values in the others, by taking into account the characteristic permeability curve of the iron, and the conditions of the measurement.

For convenience and general use, however, the secondary definition of Sumpner and Fleming[4] is probably the best to adopt, and valuations in the other two can be reduced if necessary to this when the data for so doing are available.

The inductance of a circuit or portion of a circuit, is then the ratio between the total induction through it to the current producing it. Thus taking a simple helix of five turns carrying a current of two units, and assuming that 1,000 lines of force,[5] passed through the central turn, of which owing to leakage, only 900 thread the next adjacent on each side, and again only 800 through the end turns, there would be 800 + 900 + 1,000 + 900 + 800 or 4,400 linkages of lines with the wire, and this being with 2 units of current there would be 2,200 linkages with unit current, and consequently the self inductance of the helix would be 2,200 centimetres. (Fig. 1.)

The fact that such helices are used in galvanometers, and that the magnetic force at any point within them is admitted to be proportional to the strength of the traversing current, renders it evident that had the current in this case been one unit, 2,200 lines linked with the coil would actually have been produced. Supposing, however, that the helix had been wound upon an iron core, the total number of linkages with the same two units of current would have been greatly increased, perhaps twenty-fold or to 88,000 and the inductance then by the same rule would be 44,000. In this case one unit of current would not in all probability reduce the number of linkages to 44,000, the exact number would

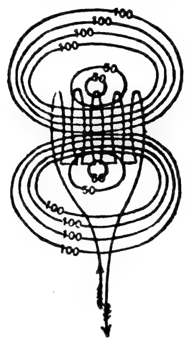

FIG. 1.

depend upon the characteristic curve of the iron core, and the degree of saturation, so that it would now be necessary to state the conditions of the measurement along with the result, in order to convey a clear and definite meaning.

It appears anomalous at first sight to state the above inductances in centimetres when they are derived from the number of lines of force, but it is to be remembered that the total number of linkages is divided in each case not by a mere numeric, but by a current, and this quotient can be proved to be a length in the existing system of dimensions.

In the same way the mutual inductance of two conductors is the ratio of the total induction through one of them to the strength of current in the other producing it. Suppose two coils of copper wire to be held in free space far from iron, and let one of them be traversed by a steady current of say four units. Of all the lines of force issuing from this coil, suppose 500 pass through the other coil. For simplicity, imagine the second or recipient coil to be composed of eight turns so disposed that the 500 lines pass through all in succession. There will then be 4,000 linkages of lines with that coil, and the mutual inductance of the two will be 4,000 ÷ 4 or 1000 centimetres. It is interesting to notice that the same result would be reached if the second coil had the current and the linkages were counted in the first, the pair being mutually conjugate in this respect provided they reside in a medium of constant permeability.

Thus far we have only considered the centimetre or absolute unit, whose unfitness for practical use is evident, since the smallest inductance that is at present known to engineering amounts to several thousand, while the average values met with are counted in millions of centimetres. It would of course be possible to name suitable units from the metrical system of lengths, but it is the proposal of this Institute to adopt the word Henry as the practical unit, in honor of the man, who beyond all doubt, was among the foremost to extend the knowledge thus far possessed of self and mutual inductance.

If the selection of the practical unit were entirely free and subservient only to practical requirements, so that its magnitude should express ordinary values in digits with fewest decimals on

5. The term line of force here is used in the sense of a line of induction; the distinction being necessary when the lines pass through iron.

the one hand, or large numbers on the other, there seems most reason to believe that the thousandth of the earth-quadrant or myriametre would be the most eligible.

Proposed Name.	Length.	Number of Centimetres.	Unit.
Henry	Earth Quadrant.	1,000,000,0000	Practical Unit.
		100,000,000	
		10,000,000	
Millihenry.	Myriametre.	1,000,000	
	Kilometre.	100,000	
	Hectometre.	10,000	
Microhenry.	Decametre.	1,000	
	Metre.	100	
	Decimetre.	10	
	Centimetre.	1	Absolute Unit.

Of course large iron machines employing many turns of wire linked by dense magnetic fields, would have inductances more appropriately expressed in earth quadrants, which might then be termed the kilo-henry just as we now have the watt, and kilowatt, but there is one restriction which makes such a selection undesirable, and that is the hitherto unbroken system of practical units itself. This practical system is a sub scheme of the great international C. G. S. system and especially planned for adaptability to practical requirements. It is derived from that parent system by the substitution for the unit of length, one thousand million centimetres in place of one centimetre, and for the unit of mass an impalpable entity definite only in thought, the one-hundred millionth of a milligramme in place of the gramme. By this substitution in the C. G. S. electromagnetic units, we obtain the hitherto unbroken system of the volt, ohm, ampere, coulomb, joule, watt, and farad. Even these units are not always the most convenient, witness for example the micro-farad in common use, whose prefix is maintained simply in deference to the harmony of the system, for the farad is a capacity that exists only in imagination; the capacity of the earth itself being only about 700 microfarads, and of the sun, or rather a sphere having the apparent dimensions of the sun, being only about 76,000 microfarads. On the other hand a proposition has lately been made to infringe the system by making the volt, the ampere and the watt, ten times their present values, on the ground of practical convenience.[6] However, at the present time, it would surely be unadvisable to attempt the precedent of infringing a system that has hitherto been supported by time, custom, and international Congress.

In this practical system, the unit of inductance must be 1,000 million centimetres. That is an earth-quadrant or the distance from the pole to the equator, measured on the meridian of Paris. Strictly speaking, it is only the quadrant of the French standard earth, which is about one-hundredth of one per cent. shorter than the acknowledged actual earth-quadrant, according to the best determinations, but the fact of the latter being 10,001 kilometres instead of 10,000, is a matter of precision in definition only and in no way affects the practical unit.

As regards the history of the subject, it would appear that prior to 1887, measurements and deductions were confined to scientific works, and were expressed in absolute units—centimetres. In that year—however, a paper was read before the British Institution of Electrical Engineers by Messrs. Ayrton and Perry,[7] who invented and developed a practical measuring instrument for the measurement of inductance, who, aided by Dr. Sumpner, made important contributions to the literature of the subject, and who proposed a name provisionally for the practical unit. That name was the secohm, a contraction of second-ohm, implying the fact that the product of the two was the length equal to the practical unit. They drew attention to the fact that since the Paris Congress of 1884 had fixed the standard legal ohm as the resistance of a column of mercury at zero Centigrade, 106 centimetres long and one square millimetre in cross section, whereas the true ohm was in all probability 106.3 centimetres, or one-quarter of one per cent. greater, the inductances measured in the manner they suggested from seconds and legal ohms, would be in terms not of the standard earth quadrant of 10,000 kilometres, but of legal earth quadrants 9,978 kilometres in length. The difference practically is not very great, but to avoid error or confusion in definition, they advocated provisionally the term secohm, in place of quadrant.

The Paris Congress of 1889 adopted the "quadrant" as the practical unit of inductance defining it as 1,000 million centimetres.

The practical range of inductances is second only to that of resistances, and the latter we know from a few microhms up to thousands of megohms. The smallest inductances are those of Hertz resonators which descend to the order of metres. Excluding these, however, the smallest are perhaps met with in measuring instruments intended to have negligibly small inductance, such as doubly wound resistance coils, Cardew voltmeters, and the like. These descend to the order of decametres, and can generally be expressed as such without prefixing decimal points. It is evident that the term microhenry would suitably apply to their designation. At the other end of the scale we find large induction machines linking dense fields with many turns of wire, and reaching inductances of hundreds or even thousands of henrys. Intermediate between these limits, there exists a large class of circuits having many turns but little iron, or clad in iron with few turns of wire, and these seem to be best expressed by the term millihenry, equivalent to the myriametre.

With the object of setting forth the advantages to be derived from the use of this nomenclature, it may be permissible to adopt it provisionally in describing the measurements that follow. These measurements have been made on different types of apparatus at different times and by different methods, so that they represent mean values from several observations in many cases, but allowance must be made for the variations of standard and type.

In telegraphy, the inductance of an ordinary Western Union 140-ohm relay is about three henrys with the armature drawn well back, and nine henrys with the armature pressed against the poles; in the latter case, of course, the magnetic reluctance of the iron circuit is a minimum, and the same current in the coils causes three times as many lines to circulate through the iron. At the position of the armature in ordinary adjustment the inductance is about five henrys.

The inductance of an ordinary standard 10ω relay is from 200 to 500 millihenrys, according to the position of the armature relatively to the poles.

The inductance of an ordinary sounder is similarly from 25 to 50 millihenrys. These inductances are the values obtained with only a few milliamperes through the coils, and since the path of the induction is largely through iron, the inductance varies with the strength of the current used. Practically, however, the variation is small within the range of current at which instruments usually operate.

SUBMARINE TELEGRAPHY.

The inductance of a mirror speaking galvanometer of the ordinary type having 2,250 ohms was found to be 3.6 henrys.

TELEPHONY.

The inductances met with in the ordinary long distance telephone apparatus are as follows:

The call bell 80 ohms and 1.4 henrys.

The magneto armature 550 ohms, and from 2.7 henrys with the plane of the coil in the line joining the poles, to 7.3 henrys when the iron core joins the poles, the plane of the coil being then at right angles to the magnetic flux.

The induction coil primary 0.28 ohm and 3.5 millihenrys.

Secondary 164 ohms, and 734 millihenrys.

The mutual inductance between the coils 60 millihenrys.

The Bell telephone receiver 75 ohms and from 75 to 100 millihenrys. The removal of the diaphragm from an ordinary telephone of this type reduces the inductance about 35 per cent. All these inductances are due to currents of a few milliamperes only. As regards the inductance of aerial line wires, it is to be regretted that measurements are not yet forthcoming, and indeed the experimental determination is attended with some difficulty, owing to static capacity and imperfect insulation. In the absence of direct measurements, theory indicates that the inductance of overhead copper wires depends upon the elevation above the ground as well as upon the diameter. In the case of iron wires as used in telegraphy, the permeability of the iron enters as an additional factor. The following table of inductances for copper wires, is based upon a formula first given by Clerk Maxwell.[9] It is to be hoped that experimental evidence may shortly be collected corroborating these results:

The inductance of iron wires, in the absence of measurements, is almost too doubtful to justify calculation, being perhaps 10 times more than the inductance of copper wires under similar conditions. The difficulty in their case lies in assigning the proper value of permeability.

ELECTRIC LIGHT AND POWER.

Dynamos and dynamo-electric machinery are of course generally characterized by large inductances.

The inductance of the field magnets of a dynamo may have any value depending on the size and voltage of the machine from one henry up to 900 henrys.

The inductance of an armature may similarly vary from 20 millihenrys up to 50 henrys between brushes. One millihenry is a fair average value of the inductance of one section of an armature. Armature inductances depend not only on the strength of the measuring current, but also upon the strength of the field, and whatever influences the permeability of the core.

The inductance of an alternating transformer varies from a primary of 400 millihenrys, a secondary of one millihenry and mutually 20 millihenrys with a transformation ratio of 20, up to corresponding values perhaps 100 times as great.

APPARATUS. THE INDUCTANCE OF RUHMKORFF COILS.

The smallest medical coil in ordinary use has five millihenrys in its primary, 100 millihenrys in its secondary, and 20 millihenrys mutually between them.

A large induction coil 19 inches long and eight inches in diameter has 0.145 ohms and 13 millihenrys in its primary, 30,600 ohms and 2,000 henrys (by two concordant methods of measurement) in its secondary, and 163 henrys mutually between them.

The inductance of a mirror galvanometer may vary from a few millihenrys up to 10 or more henrys according to its resistance. Two henrys is a fair average for an astatic mirror galvanometer of 5,000 ohms.

An ordinary electric bell of 2.5 ohms resistance was found to have an inductance of 12 millihenrys.

There is one point in connection with the self and mutual inductance of induction coils and transformers, that deserves attention owing to the confusion that occasionally arises concerning it. It may be, perhaps, best represented by a numerical example. Let a closed Faraday ring of iron 100 centimetres in mean circumference and 20 square centimetres in uniform cross section, be closely wound with a primary coil of 2,500 turns in one layer, followed by a secondary coil of 7,500 turns also in one layer. If now two amperes be maintained steadily through the primary, the magnetic force in the iron will be $4\pi/10$ times the ampere-turns per centimetre of the iron circuit or $4\pi/10 \times 2 \times 2{,}500 \div 100$ or 62.85. The permeability of wrought iron at this force being, say 250, the induction developed per square centimetre will be 250×62.85 or 15,713 lines, and the total induction enclosed by the primary coil, neglecting the space occupied by the wire itself will be $20 \times 15{,}713$ or 314,250 lines which traverse every turn of both windings. The linkages with the primary will be $2{,}500 \times 314{,}250$, or in round numbers 786,000,000 and referred to one absolute unit of current (ten amperes), five times this number, or an inductance of 3,930 million centimetres, that is, 3.93 henrys. Similarly the linkages of these lines with the secondary will be 2,358 millions, and for ten amperes of primary current 11,790 millions of centimetres mutual inductance or 11.79 henrys. Next suppose the primary current interrupted, and a current steadily established in the secondary sufficient to produce the same magnetic force in the iron, thus avoiding the complication of a changing permeability. As the secondary has three times as many turns, the current effecting this will be two-thirds of one ampere. The total induction through the iron will now be the same as before and therefore the linkages will be equally numerous. The self inductance of the secondary will be $2{,}358{,}000{,}000 \div \frac{1}{15}$, or 35,370,000,000 centimetres, that is, 35.37 henrys. The mutual inductance will similarly be $786{,}000{,}000 \div \frac{1}{15}$, or 11.79 henrys, as before. It will be found on carrying the reckoning to the necessary degree of accuracy, that this mutual induction 11.79 is the square root of the product of the two self-inductances, 3.93×35.37.

Examination of the steps in this calculation will show that this proposition must hold for all closed magnetic circuits uniformly magnetized to the same degree when the space occupied by the windings is not taken into account. Under the opposite conditions of open and especially of short iron cores, with large winding spaces, the condition usually fails, and the mutual inductance may be greater or less than the square root of the self-inductances multiplied together.

Another reason in favor of selecting 1,000 million centimetres as the value of the practical unit or Henry, is the desirability of having the time-constant of an electromagnetic circuit expressed directly in seconds by its practical units as in the case of electrostatic circuits, rather than revert to a unit of inductance that would yield the time constant in milliseconds or other fractional period of time. The time-constant of a simple electromagnetic circuit, a circuit having inductance and resistance but negligibly small electrostatic capacity, is defined as the ratio of its inductance to its resistance, that is, of its henrys to its ohms. It is an important function, and its consideration presents some remarkable analogies between inductance and electrostatic capacity that it is interesting to trace.

Imagine an inductance coil C without iron to be supplied with a steady current from an electromotive force E of 50 volts. Let the inductance of the coil be three henrys, and its resistance 10 ohms. (Fig. 2.) Ohm's law determines the strength of the current to be five amperes. Now short circuit the terminals of the coil very suddenly by a wire across its terminals of negligible resistance. The current in the coil C does not stop instantly, but under the name of extra current is maintained in the coil by reason of its inductance. According to theory, the last dregs of the current will never entirely vanish from the coil, although after the first few seconds the remainder is exceedingly small. The very first instant after short circuiting, the current continues at five amperes by its electro-magnetic momentum, but being unsupported, its energy is lost thermally in overcoming the coil's resistance, and it immediately falls. In falling, the lines of force linked with the circuit and sustained by the current, are drawn in, cutting the coil as they recede, thus creating a counter E. M. F. tending to prolong the current, and this process of dwindling current with reduction of opposition from the reserve of inductance, descend together. The total quantity of electricity that will flow through the circuit under the conditions specified, may fairly be called the charge or discharge of the coil, and it can be readily proved that this charge is equal to the quantity that would be conveyed by the initial discharging current, acting uniformly during a time equal to the time-constant of the circuit. In this case the discharge commenced at five amperes, and the time-constant is 0.3 se ond, so that the total discharge will be that due to the flow of this current in 0.3 seconds, that is 1.5 coulombs.

To represent the case graphically, suppose the curve of discharge in time to be plotted as in the figure. Let the axis OX be divided off into seconds, and the axis OY into amperes. (Fig. 3.) The discharge commences at five amperes, subsides rapidly at first, but at last so slowly that an indefinitely long time must elapse before it altogether disappears. The area enclosed between the curve and the axis represents ampere-seconds or coulombs to the amount of the total charge, and the proposition just stated asserts that if the current had continued at five amperes steadily for 0.3 seconds, the area of the dotted rectangle so generated YDTO would be equal to the total area enclosed between the curves and the axes prolonged to the ultimate point of union.

Curiously enough, exactly the same law applies to the discharge of a condenser through a circuit of resistance but negligibly small inductance. The time-constant of the circuit in this case, however, being its capacity in farads multiplied by its resistance in ohms.

The curve of discharge is of the same type for inductances or capacities. It is logarithmic, and finds its prototype in the case of the discharge of water in time, from a tank having a faucet at the base, assuming that the rate of escape through the faucet at any moment is directly proportional to the pressure, or level of water then remaining in the tank.

The laws which control the outline of this discharge curve are identical for condensers or short circuited inductances, and are combined in the following enunciation:

The natural logarithm of the ratio of the $\left\{\begin{matrix}\text{full charge}\\ \text{initial current}\end{matrix}\right\}$ to the $\left\{\begin{matrix}\text{residual charge}\\ \text{discharging current}\end{matrix}\right\}$ at any instant is the quotient of the time during which discharge has been in progress by the time constant of the circuit.

In this statement two reservations are necessary.

The electrostatic circuit must be free from all appreciable inductance, and the electro-magnetic circuit must contain negligibly small electrostatic capacity. It was first pointed out by Sir William Thomson that the discharge of a condenser through an inductance circuit, becomes oscillatory when the inductance exceeds a certain critical value.

When an inductance discharges through a break instead of a closed circuit, the conditions become complicated to a degree that eludes complete practical solution in the present state of knowledge.

At the period of natural discharge equal to the time constant, an inductance or capacity charge or current will have fallen to 36.8 per cent. of its initial value.

Similar propositions relate to the charging currents and quan-

tities. In the above instance, after the coil has completely discharged, remove the short circuiting wire. The current will immediately enter the coil, and the curve of its arrival in time is represented in Fig. 4, this curve being only an inversion of the preceding. For this reason it is evident that the area above the curve now represents the charge, and by an extension of meaning, the deficit from full current, such as BC, may be called the charging current, since on discharge and reversal of the diagram, this will be the discharging current at the same lapse of time. In fact, the current AC is doing work in heating the coil, the deficit from ultimate current BC being only active in increasing the electro-magnetic momentum of the circuit, and work is really stored in the coil as though the deficit current did exist. A similar but inverted curve of current in time represents the charge of a condenser. In each case and under the above restrictions the following propositions hold:

The natural logarithm of the ratio of the $\left\{\begin{matrix}\text{full charge}\\ \text{initial current}\end{matrix}\right\}$ to the $\left\{\begin{matrix}\text{deficit from full charge}\\ \text{charging current}\end{matrix}\right\}$ at any instant is the quotient of the time during which the charge has been in progress by the time constant of the circuit.

When the charging interval reaches the time constant, the charge will have attained 63.2 per cent. of its full value.

Another relation between simple electrostatic or electro-magnetic circuits and their time-constants is in their stores of energy. The energy of the charge in each case is half the energy that would be developed by the initial charging or discharging current against the ohmic resistance of the circuit in the time equal to the time-constant. In the above instance for example, five amperes being the initial charging or discharging current, and

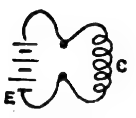

Fig. 2

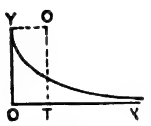

Fig. 3

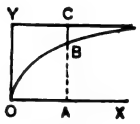

Fig. 4

the resistance 10 ohms, the circuit energy of this current per second would be $5\times5\times10=250$ joules, and during half the time-constant the energy thus developed would amount to $0.3\times250\div2$ or 37.5 joules. This is the electro-magnetic energy stored up in the charge.

These are not the only analogies that exists between inductance and capacity, but there are remarkable points of diversity. The discharge of extra current of a coil is in the same direction as the circuit current, with the condenser it is the reverse. In a great many practical instances, the electro-magnet and the condenser are used to annul each other's influence.

The time-constant of an inductance circuit is generally small for the reason that a coil of large inductance has generally many turns and therefore high resistance, so that the ultimate ratio of the henrys to the ohms is not large. For example, the time-constant of a Bell telephone, considered in itself or on short circuit, is from the measurement above described, about $0.09\div75$ or 0.0012 seconds, and therefore a steady E. M. F. of, say, two volts, impressed directly upon such a telephone would produce in this interval of time 63.2% of 2/75 amperes, namely, 169 milliamperes. By adding inductanceless resistance to the circuit, however, and raising the E. M. F. proportionately, the time-constant would be lessened, and the arrival of current accelerated. Strictly speaking this reasoning is inaccurate, since the telephone coil surrounds iron, but with the small currents usually employed, the iron probably does not greatly influence the arrival curve. In the case of dynamo field-magnets, and large ironclad inductances generally, the divergence of the arrival curve from that of a corresponding simple electro-magnetic circuit is considerable.

There are several methods by which self and mutual inductance can be measured, the selection depending on the magnitude to be determined and its nature. The Ayrton and Perry secohmmeter or double revolving commutator is perhaps the most generally useful. It may be employed in connection with a standard condenser, a standard inductance, or apparent change of resistance with speed. Being used in the Wheatstone bridge, the currents it can alternate are necessarily limited in strength.

For small inductances,[10] say, less than one-tenth of a millihenry, the method of Professor Hughes[11] or its modification by Lord Rayleigh is probably best suited, using two coils of mutual inductance and a telephone as the observing instrument.

The inductance coils are usually in the form of two concentric rings, the inner being capable of rotation about the common vertical. The mutual inductance of such a pair of coils is a complex function of the dimensions and the angles between the planes at which the coils may be set. It is usual to calibrate the instrument by separate measurements of the inductance at different angles. A simpler arrangement however, for mutual inductance is a short solenoid in the bridge circuit superposed coaxially upon a long solenoid in the battery circuit. Adjustment to silence in the telephone for interrupted currents is then made by including in the bridge circuit a greater or less number of turns in the outer solenoid. The mutual induction is then very nearly proportional to the number of turns so included, and by suitable proportions in construction, the accuracy can be carried as far as the telephone for the receiver will permit.

For the measurements of inductance in coils on iron machinery, the ballistic galvanometer is frequently employed, either by the method of discharge for self inductances, or induced quantity with mutual inductances. Mutual inductances connected by closed iron circuits present no difficulty when great accuracy is not required, since, as already observed, the self inductances are calculable in these cases when the mutual inductance and the number of turns in the coils are known. It is much more difficult, however, to measure the self-inductance of the field-magnet of a dynamo when the armature is removed, and when currents of the normal exciting strength are used in the measurement. The best attempt has been made apparently by observing the discharge effects of gradual small changes of a strong current passing through the coil, in circuit with a specially arranged Wheatstone bridge.[12] If it were of sufficient practical importance, however, to measure such inductances with powerful currents, a recording instrument might be tried, having a very light and swiftly moving pointer, leaving a trace of its motion on a strip of moving paper like Sir William Thomson's siphon recorder. If such a pointer was arranged to give an amplitude of movement at right angles to the paper strip, in proportion to the current traversing the coil, it would register the curve of discharge when the coil was short-circuited, in the manner described above. On a sufficiently enlarged scale, corrected perhaps for residual inertia in the moving parts, this curve would give not only the total quantity of discharge, but its deviation from the logarithmic line of simple electro-magnetic discharge, would give the means of determining the characteristic of magnetization in the iron.

Of far lesser importance than the selection of the practical inductance unit, but still well worthy of separate consideration is the selection of appropriate symbols to represent the unit briefly. It might perhaps be advantageous to represent the henry by a capital H., and the millihenry by the plain letter h. This notation would enable such an inductance as 50 henrys to be written as 50 H, and 50 millihenry as 50 h. The microhenry occurs so seldom that it would probably not need a symbol.

All measurements of precision should employ true ohms and not legal ohms in the computations. The best existing value of the true ohm is 1.0028 legal ohms.[13]

The correction is practically so small that it can best be carried out by altering the nominal standard temperature of the resistance coils adopted. These temperatures should be increased by 9.4°C for platinum-silver, 6.5°C for German-silver, and 13.5°C for platinoid. Thus a resistance box with platinum coils standardized for legal ohms (of 106.0 cms.) at 15°C would give true ohms of 106.3 cms. at 24.4°C as the best approximation, and this would be the standard temperature of the box for use in precise measurements of inductance.

STORAGE CARS FOR WASHINGTON.

It has been definitely determined by the Metropolitan Street Railroad Co., of Washington, to change its motive power from horses to electricity, and the storage battery system has been adopted, Mr. C. O. Mailloux, the well-known electrical engineer, being engaged to carry out the work and to embody all possible improvements in methods of construction and operation. Mr. Mailloux has already had a storage car running with much success over the company's lines, and now has the task of getting 40 cars ready for service, with full equipment. The company voted on Dec. 11 to increase its capital stock $500,000 to carry out the change, and will proceed to build two power houses, for one of which, to run the F street line, property has just been secured. All the cars will be new, and all the tracks, too, 60lb. grooved rail being now in course of laying. The directors of the Metropolitan Railroad Company, upon whom will devolve the execution of this plan that means so much for the cause of rapid transit in Washington, are Messrs. George W. Pearson, president; A. A. Wilson, vice-president, and Dr. Daniel B. Clark, John Cammack, A. A. Thomas, Robert Beall, and Robert D. Weaver.

MR. W. F. SHERMAN.—The death is announced at Lowell of the above-named inventor, who was greatly interested in questions and problems of rapid transit.

EUROPEAN CORRESPONDENCE.

LONDON.

Electric Lighting of a Thread Factory.—Meetings of Companies.—Telephones.—Trial of Electric Meters.—Paris Companies.—Watt vs. Maxim Weston.—Paper on Electric Lighting Progress.—Tramways.

THE whole of the immense buildings used by Messrs. Barbour & Co., Hilden, Ireland, for the manufacture of thread have been fitted throughout with electric light. As showing the gigantic scale of this concern, one may mention that the buildings occupy a space of thirty-five acres, and over 5,000 workers are employed.

The meetings of electrical companies have been numerous during the past few days. Fowler Waring Cables shareholders dropped in to ascertain the date of probable dividends. The chairman met them with statements of delays (not specified), which were now overcome, a good factory had been secured, an able manager was running it and the directors expected from that day there would be nothing but plain sailing. It is a remarkable fact that the position of a company looks brighter and sounder on the day of the annual meeting than at any other period subsequent or previous.

The Electric Construction Corporation held its first annual meeting on Monday. The chairman, Sir H. Mance, remarked that the company possessed patents of undoubted value, which although undeveloped, would in the hands of subsidiary companies now formed, prove a solid source of income. Upon paper their transactions looked very flourishing indeed, but he hoped shareholders would support the policy of the directorate in the decision not to apply any profits of the sales of patents to the credit account, until the patents had been written off. They were carrying on at Wolverhampton and Millwall continuous experiments. A notable one was the extraction of phosphorus by means of electricity. In view of the progress of electric lighting in England and probable contracts, it was decided in order to secure increased business to make an issue of £100,000 of debentures bearing six per cent.

Reuter's Telegram Company are taking advantage of that clause of articles of association which enables any commercial undertaking to make money out of work as widely different as the supply of public electric lighting and the washing of private linen. It is intended to take up an international advertising agency by means of their cables.

The National Telephone Company will pay in a few days a dividend of five per cent., which is the last before the expiring of the patents held by them with peculiar injudiciousness for a good many years. During this period the bearing towards customers has slowly if silently created a host of enemies whose ill feeling and bitterness will act with great influence on future developments of this concern. Their position is analogous to that of King John, and the charter of liberty for the users of the telephone may be said to date from July of 1891. In answering a question in the House of Commons, on Monday, with reference to the telephones, Mr. Raikes, the Postmaster-General, expressed a hope that he would be able before long to announce the decision of the Government with regard to licenses for telephone exchanges.

Last year a trial of electric meters took place in the city of Paris, which was postponed to this year. There are now fifty sets of apparatus which are to compete for the first place. The jury selected to examine the instruments will be composed of nine members, of whom five are chosen by the Municipal Council.

Parisian electric lighting companies which recently obtained concessions for 18 years are anxious to prolong the period to 1930, and as an inducement offer to lower the price charged for current.

Watt *vs.* Maxim-Weston Electric Co. is no new feature in the English law courts. This is the *Watt* which the unfortunate company could not manage with any degree of success, and dispensing with his services, actions were brought against them for monies due for salary, damages, wrongful dismissal, etc. Any one acquainted with the sad history of the Maxim Weston patents in England, cannot fail to see that many of its misfortunes were due to the connection with Watt. It marks an epoch in the records of gross mismanagement, and strong opinions have been given from the judicial bench on this subject. What appears to be the final action has been concluded; the case was three days in the courts, at the end of which the judge suggested that some arrangement should be made. The counsel met in consultation and agreed to compromise the matter. Thus ends the last act of drama of the Maxim-Weston Co., which has lived for no one's benefit save the lawyers'.

To-night a paper will be read before the Society of Arts on "Electric Lighting Progress in London," by Mr. F. Bailey, engineer to the Metropolitan Electric Supply Co. The paper will no doubt be most interesting, as the lecturer's position enables him to deal with the subject in a trustworthy manner.

The North Metropolitan Tramways Co. have received the consent of the County Council to run electric cars over the northern portion of its line controlled by the Council for a term of seven years. The Tramway Co. has also given notice of a bill which it intends to introduce into Parliament asking that the local authority be compelled to conform to the Act passed last session giving tramway companies a full term of seven years guaranteed by the Act. At present the West Ham local authorities decline to grant more than one year's license subject to twenty-four hours' notice.

The General Electric Power and Traction Co. are offering to the tramway companies to supply cars and the electrical equipment and to maintain the motors, switches, gearing and accumulators at a mileage rate, the tramway company operating the road at their own expense.

LONDON, Dec. 10, 1890.

CORRESPONDENCE.

CHICAGO.

Evanston Objects to Telephone Wires.—A Street Railway for Tolleston.—A Big New Apartment Building.—Electric Club Dancing Parties.

AT the village board meeting at Evanston, last week, the Chicago Telephone Co. was charged with erecting poles on Ashbury avenue, without the knowledge of the board and an order has been served upon it forbidding all further work of extension in the village until the poles are removed to some more suitable route to be designated by the board.

The Board of County Commissioners of Lake County, Indiana, at its December session, granted a right of way over the highways between Crown Point and Tolleston to the Crown Point and Indiana Stock Yarks Street Railway Co. The company, composed of Crown Point capitalists, headed by W. C. Murphy, proposes to build an electric street railway line directly north from Crown Point along the section line road to Tolleston, and on to the town to be established by the packers. This line when finished will be about one and nine-tenths miles in length.

A large apartment building is to be erected on the northwest corner of Cottage Grove avenue and Fortieth street, at a cost of $225,000. It is to be seven stories high, with steam, electric light throughout and elevator service.

The first of a series of informal dancing parties to be given by the Chicago Electric Club, will take place December 26th, 1890, commencing at 8 o'clock. The club rooms will be used for the purpose of reception and cloak rooms, while as the committee, in their circular, naively put it "the light fantastic will be tripped in the most approved electric club manner to the music of Pound's full orchestra in Kinsley's Banquet Hall." It is hoped that every member will attend and bring his friends, thus maintaining the recognized social and hospitable standing of the club.

CHICAGO, Dec. 20, 1890.

BOSTON.

Fire Department Wires.—Lighting Up a Store Front.—New England Printing Tel. Co.—West End Power Station.

INSPECTOR OF WIRES FLANDERS has commenced operations by making a number of changes in the fire alarm department.

It is estimated that there are over 5,000 miles of overhead wires it this city, 525 miles of which belong to the fire alarm department. Of this amount of wires a large percentage is known as "dead wires," and Supt. Flanders will at once begin the work of removal.

The fire alarm system of Boston was the joint invention of Dr. W. F. Channing and Prof. M. G. Farmer, both of whom are now living. The system was put in operation April 28, 1852, and was the first electric fire alarm system in the world.

Messrs. Houghton & Dutton, one of the enterprising dry goods firms of this city, have made a very striking display of electric lights on their store as a Christmas greeting.

Both the Tremont street and the Beacon street sides of the structure were hung from top to bottom with three rows of red electric lamps, while in the centre the device gleamed forth in large letters:

HOUGHTON
and
DUTTON.
MERRY
CHRISTMAS.

No less than 530 electric lights were used in making the mammoth display.

The New England Printing Telegraph Company has completed its line from Providence to Boston, and will soon be ready to do

business between these two cities. The line also communicates with Woonsocket, R. I., and Pawtucket, R. I. The writer had the pleasure this week of sending an important message from Providence to Boston, which was speedily and expeditiously attended to.

The West End Street Railway Co. are rapidly pushing ahead with their power station, and have nearly ready for use two batteries of boilers. The foundations for the temporary engines and generators to be placed in the boiler house are almost ready and preparations are being made for their reception.

The 252 feet chimney stack is now complete and rears its head proudly over anything in Boston, and this week one of the lightning rods was safely attached to its side. The writer had the pleasure one day this week, of ascending to the top, whence a magnificent view of the surrounding country can be had. The inside diameter at the top is thirteen feet, and it is difficult to imagine, when one is walking around the platform on top, that such a large aperture is necessary, and that one is on the top of a chimney stack. The new Robinson radial cars are commencing to arrive now, and inside of a month or two there will be about fifty of these in service. Work is being actively pushed on the plans for the elevated road, though no decision has yet been arrived at as to the actual route through the city, permission not having yet been granted for the Harrison avenue extension.

BOSTON, Dec. 19, 1890.

PITTSBURGH.

The Great Snowstorm.—Affairs of the McKeesport Light Co.—Local Light Companies Are Not Manufacturing Concerns.

PITTSBURGH has been visited by a terrific snowstorm, and since last Wednesday the streets have been almost impassable. The Signal Service officers stated that this city never had a snowstorm like it in severity and it may be easily imagined, that the effects it had were considerably damaging. In this respect it is certain that nothing suffered so much as the electric wires. According to the latest estimates the Western Union Telegraph Co. and the District Telephone Co. alone had their systems damaged to the extent of $50,000. It is therefore safe to presume that the electric light, the electric street railway and the cable companies were also heavy losers on account of the storm. There fell altogether 26 inches of snow within 24 hours. The telegraph, telephone, electric light and electric street railway wires were covered with snow until the load often became too heavy and they snapped. In many instances where the wires did not break, the poles gave way under the heavy weight of snow and wires. The result throughout the city presented on Wednesday a complete scene of demoralization as far as wires were concerned. In several portions of the city the light wires were damaged and in the evening the streets were dark. The "Hello" through the telephone was a futile attempt, because "Central" could not receive. Owing to the snow and slush in the streets as well as the condition of the wires the electric roads had to suspend business altogether for the greater part of last Wednesday. But the cable and the horse cars could not be operated either, because the streets were impassable to any vehicle. A number of accidents were also caused by the broken wires, but considering the enormity of the damage done accidents were very few. Two horses were killed by a current from a street car wire and the driver was knocked off his seat, but that was about all that happened. Out of 3,500 telephone wires 1,000 were broken down. The repairs are estimated to cost $25,000.

Judge Ewing, of this city, yesterday refused the mandamus asked for by Thomas A. Edison and others of the McKeesport Light Co. against a minority of stockholders, who prevented the election of officers. The judge thought the minority should not rule, but he held that the application of the plaintiffs was not properly presented and he therefore refused to grant the mandamus.

In the case of the Commonwealth of Pennsylvania *vs.* the Brush Electric Light Co., of Philadelphia, Judge Simonton at Harrisburg, yesterday banded down an opinion, holding that the electric light companies are not manufacturing corporations, and consequently are taxable on their capital stock. The defendant company claimed that it was not only a manufacturing corporation, but that the general revenue act of 1889 was unconstitutional, because it lacked equality and uniformity. Judge Simonton also decided the latter part in favor of the Commonwealth, thus affirming the constitutionality of the tax on capital stock, which amounted last year to nearly one million dollars, all of which would appear to have been illegally collected had this decision been otherwise. The case will be appealed to the Supreme Court.

PITTSBURGH, Dec. 19, 1890.

COLLEGE NOTES.

DEPARTMENT OF ELECTRICAL ENGINEERING—PRINCETON COLLEGE.

We have received an advance proof of a very pretty and neat little pamphlet setting forth the electrical course at Princeton and the various agencies and apparatus provided there for students in electrical engineering. It is illustrated by photogravures of the Observatory Building, the Main Laboratory, the Reading Room, the Dynamo Building, and the Engine Room, the pictures being excellent. The facilities for experimental work are evidently abundant.

The course in electrical engineering at Princeton occupies two years, and the John C. Green School of Science furnishes a course in mathematics, physics and modern languages, which is especially arranged to meet the requirements for entrance on the electrical course. The requirements for entrance are the same as those of the Department of Civil Engineering, which is completed at the end of the third year. Applicants who have not taken this course are not admitted unless they give evidence of suitable preparation in mathematics, physics and general chemistry, these studies being considered essential preliminaries. If the applicant is deficient in analytical mechanics, drawing, or modern languages, an opportunity will be given him to take suitable courses in those studies in the School of Science.

THE PRATT INSTITUTE, BROOKLYN.

The first term of the course of lectures and experimental work given to the class in electrical construction of the Pratt Institute, Brooklyn, ends on December 19.

The work in the department has been carefully planned with the view of giving the students, first, a theoretical knowledge of the principles of electricity, and then tracing the practical application of these principles to the various branches of electrical engineering and construction.

The class is mainly composed of young men employed in various electrical industries, who have availed themselves of an opportunity to better their education in the electrical field while still attending to their daily duties. The general supervision of the class is under Mr. C. R. Richards, Director of the Mechanic Arts Department of the Pratt Institute, while the students are under the immediate care of Mr. F. W. Dunbar, graduate of the Massachusetts Institute of Technology.

The first term's lectures have consisted principally in a drill of the fundamental laws of the electric current and magnetism, leading up to the application of the electro-magnet to the dynamo. Tables of specific resistances, primary battery E. M. F's. and resistances, etc. have been furnished to the class in a form the most convenient for practical use, and the essential laws and formulæ of electro magnets presented as clearly as possible. Attempt has been made to keep up to the present times in both the theory and practice of electricity.

The laboratory work has consisted in a personal demonstration by each student of the laws stated in the lecture room, including the laws of permanent and electro-magnets, relations of current, electromotive force and resistances, and a thorough drill on the Wheatstone bridge. Each student keeps the results of his own experiments carefully written in his note book, which is subject to the inspection and criticism of the head of the department. Power and battery current are available for use in both laboraratory and lecture room.

The second term, beginning January 5, 1891, will be occupied with the practice and application of power electricity, including incandescent and arc lighting, stationary motor and tramway work and transmission of power. Considerable time will also be spent in a practical course on telegraphy and telephony.

A direct current motor and dynamo and alternating dynamo will be used in the laboratory for experimental work by students during the coming term, and every possible facility given to the young men to broaden their practical knowledge of modern electrical construction.

ELECTRICAL LECTURES AT COLUMBIA COLLEGE.

The following course of evening lectures on "Practical Electricity," fully illustrated by experiments, will be given at Columbia College, by Francis B. Crocker, E. M., and Michael Pupin, Ph. D., the instructors in electrical engineering, on successive Thursdays, at 8 o'clock, commencing Jan. 15, 1891.

1. General Principles of Electricity, showing principal ways of producing it and effects produced by it.
2. Electro-magnetism.
3. Electrical Units and ways of measuring electricity.
4. Dynamo-electric Machines.
5. Electric Motors and transmission of power.
6. Electric Lamps.
7. Alternating Current Electricity.

8. The Telegraph.
9. The Telephone.
10. Storage Batteries.

These lectures are intended to give a reasonably intelligent idea to professional and busines men of the most important practical applications of electricity.

The fee for the course has been fixed at $10 payable in advance. Persons desiring to avail of this opportunity must register their names in the president's office on or before January 10, 1891, and pay the fee at the time of registration.

Should the number of applicants exceed the accommodations of the lecture room, preference will be given to those who register earliest. Tickets will not be issued to a greater number than can be accommodated with seats. It will not be possible to obtain admission to single lectures or to a part of the course at a reduced fee.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The fifty-second meeting of the American Institute of Electrical Engineers, was held at the house, 12 West 31st street, on December 16, the attendance being very large. The "Henry" committee reported in favor of keeping the new unit as the equivalent of the "quadrant." Mr. A. E. Kennelly read the paper printed elsewhere in this issue on "Inductance and Its Proposed Unit the Henry." Discussion on both report and paper was postponed until the meeting of January 20, 1891. Mr. Emile Berliner, the inventor of the machine, then read a paper on the gramophone, accompanied by a full programme of musical and other records made by the gramophone. A record was also taken and etched in sight of the audience and afterwards reproduced in the machine. The description of this ingenious invention was listened to with close astention, and the reproductions elicited hearty applause. At the close the apparatus was thrown open to inspection, and several of the etched plates were carried away as souvenirs. One of the most interesting numbers of the programme was the rendering of Oxenford's baritone "Man-O'-War Song," on the gramophone, with direct piano accompaniment by Mr. George H. Guy. The experiment was very successful and pleasing, the two instruments being played, so to speak, in admirable accord.

At the meeting of the council on Dec. 16, the following gentlemen were elected to associate membership, bringing the total of members in good standing to over 500. There were also seven transfers to full membership.

P. H. Alexander, president Alexander, Barney & Chapin, 20 Cortlandt street, New York City.

Charles E. Dressler, maker of scientific and electrical apparatus, College of the City of New York, 17 Lexington avenue, New York City.

E. L. French, draughtsman, Mather Electric Co., Manchester, Conn.

Arthur Handley, electrical engineer, Electrical Engineering Co. of Ireland, L't'd. 61 Dawson street, Dublin, Ireland.

George Mayer, mechanical draughtsman, Edison General Electric Co., 68 Broad street, New York city.

Wm. F. Murphy, electrician, Spartanburg Electric Light and Power Co., Spartanburg, S. C.

F. B. H. Pain, consulting electrical engineer, Chas. Pain & Sons, 71 Broadway, New York city.

Chas. Lane Poor, tutor, College of the City of New York, 17 Lexington avenue, New York city.

Samuel Sheldon, A. M. Ph. D., professor of physics and electrical engineering, Polytechnic Institute, Brooklyn, N. Y., residence, 20 Sidney place.

Wilfred J. Spruson, member of the firm of Hepburn & Spruson, consulting engineers and electricians, 169 King street, Sydney, Australia.

M. C. Sullivan, with THE ELECTRICAL ENGINEER, 150 Broadway, New York city.

John Waring, consulting electrician, The Perkins Electric Lamp Co., Manchester, Conn.

"ELECTRICAL UNITS" AT THE ELECTRIC CLUB.

"Electrical Units of the Present and Future," was the subject of a lecture delivered on December 18, before the Electric Club, by Prof. Francis B. Crocker, of Columbia College, who showed the real meaning and the way of determining the numerous electrical units, such as the volt, ampere, ohm, etc., which, though in common use, are not understood even by many electrical men. The subject of a name for the new unit of self-induction was also discussed. Prof. Crocker has proposed that the new unit should be called a "Henry," after Prof. Joseph Henry, and it is thought that this name will be generally adopted. If it is adopted it will be the first American name for an electrical unit. Prof. Crocker made his lecture extremely interesting, accompanying it with a large chart and with examples of the standard units, such as the B. A. ohm, Clark cell, etc.

The club, before listening to Prof. Crocker's lecture, amended its by-laws, increasing the limit of membership to 1,000. A change in the dues was also made, so that hereafter active or voting members will pay $40 and associate members $20 a year. Life memberships in the club cost $500, and about twenty have already been taken.

REPORTS OF COMPANIES.

EDISON GENERAL ELECTRIC CO.

The stockholders of the Edison General Electric Light Company have been notified that the fifth quarterly dividend of 2 per cent. on all the stock of the company, including such stock as is held in trust by the Farmers' Loan & Trust Co., has been declared payable February 2, to holders of record December 29. The payment of the dividend on stock held in trust, is, however, subject to the ratification of the action of the trustees in dissolving the trust, by the stockholders at their regular meeting on January 19, next. A special meeting of stockholders will be held on the same day for the purpose of voting upon a proposition to increase the capital stock from $12,000,000 to $15,000,000.

STATUS OF THOMSON-HOUSTON STOCK.

The Thomson-Houston Electric Co. make the following announcement: "The sale of the 60,000 shares at $50 per share was absolute and complete. The subscriptions received at the time, as was then well understood, were largely in excess of the amount allotted; 10,000 shares were sold and paid for in cash; 50,000 shares were sold at $50 per share, payable one-third in October, one-third in January and one-third in April, with interest at 6 per cent. from October 1. Somewhat more than one third of the 50,000 shares were paid for in October. The total amount received by the company on account of this sale is at the present time a little in excess of $1,600,000. There has been no delivery of any stock for which payment has not been received in full in cash. The Thomson-Houston Co. realizes net $49 per share after paying all commissions, discounts and expenses in connection with the transaction. In addition to the amount to be received by the company from the sale of stock in January and April, aggregating about $1,400,000 within that time, the company will also receive in cash from the sale of securities to the United Electric Securities Co. $450,000. The company has $6,000,000 more assets than at the end of its last fiscal year. It has $1,250,000 less liabilities. With unsecured debts of less than $50,000, its entire indebtedness, less cash on hand, is scarcely more than the amount of cash to be received by it as above indicated between now and May 1. There is no reason why any creditor or any stockholder should remain in ignorance of any essential facts concerning the condition of the Thomson-Houston Co. Its affairs are always open to the inspection of anyone who has a right to make any inquiries concerning them."

AFFAIRS OF THE WESTINGHOUSE CO.

Westinghouse stock was quoted in Pittsburgh on Wednesday last at 13¾ bid and 14¼ asked. The Pittsburg *Telegraph* of December 17, reports that at that time, the committee having in hand the raising of money to assist the Westinghouse interests had raised all but $30,000 of the $500,000, and that the committee had no doubt that the whole amount would be secured the next day. It is understood that the whole sum has since been subscribed.

DIVIDENDS.

BOSTON MASS,—The Edison Electric Illuminating Co., of Boston, has declared a quarterly dividend of 1 per cent. payable January 15.

THE AMERICAN BELL TELEPHONE directors at their meeting declared the regular quarterly dividend of $3 a share, but took no action whatever in regard to any further issue of stock.

STOCKS AND BONDS.

HOLYOKE, MASS.—The Holyoke Street Railway Co. will increase its capital stock from $50,000 to $150,000 and adopt electricity as motive power.

EASTON, PA.—The Edison Illuminating Co., of Easton, is about to double the capacity of its plant, and has voted to increase its capital stock from $100,000 to $200,000.

MINNEAPOLIS, MINN.—There is a split in the Electro-Matrix Co., and two sets of directors have been elected.

ATTLEBORO, MASS.—One of the most successful electric roads in this country is the new Attleboro & North Attleboro railway, which carries 1,200 passengers a day in territory in which there are not over 15,000 people. The line competes with a steam dummy line, and the stock sells at $165 a share.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DEC. 16, 1890.

Alarms and Signals ;—

Means for the Transmission of Meteorological Indications, H. J. Haight, 442,881. Filed Nov. 29, 1889.

Improvements upon devices previously patented by the same inventor for the transmission of meteorological indications from a main or central observatory to distant receiving stations. The object of the present invention is to reduce the number of indicating instruments at the several stations, and the invention consists chiefly in means employed for enabling a plurality of indications to be exhibited successively upon indicating instruments less in number than the number of the indications.

Multiple-Circuit Closer, H. J. Haight, 442,882. Filed March 14, 1890.

The invention relates to devices which enable a plurality of indicating instruments to be brought one by one into electric communication with a single source of electricity, by which all the indicating instruments may be controlled by a single switch or key.

Conductors, Conduits and Insulators :—

Underground Conduit for Electric Conductors, J. S. DuBois, 442,868. Filed Mar. 15, 1886.

The conduit consists of an enclosure of asphalt or brick surrounding a frame secured therein and provided with supporting brackets, and anchor pieces, for the support of tubes or troughs upon the brackets ; the tubes or troughs are provided with longitudinal slots and flanges on their upper sides, the flanges serving to secure the tubes in position.

Dynamos and Motors :—

Portable Electric Motor and Cloth-Cutting Machine, E. D. Weyburn, 442,654. Filed Apr. 5, 1890.

Adaptation of electric motors to operate cloth-cutters in large clothing factories and similar establishments. The motor is suspended from a track passing above the cutting tables and the cutter is actuated through a flexible shaft.

Regulation of Electric Motors. E. W. Rice, Jr., 442,668. Filed Oct. 20, 1890.

Replaces the resistance coils usually employed for insertion in the armature circuit of an electric motor, upon starting, by coupling in series circuit with the armature, when starting from a state of rest, a counter potential generator. The counter-potential generator is maintained in circuit until the speed of the armature becomes such as to generate of itself sufficient counter-electromotive-force to render injury from the passage of an excessive current no longer liable to occur.

Dynamo-Electric Machine or Motor, N. H. Edgerton, 442,870. Filed Oct. 22, 1890.

Design and construction for cheapness, simplicity and compactness. The frame forms a double yoke for the field-magnets and consists of two sections, one forming three sides and the other forming the fourth. The frame is formed with oppositely-located bearings for the amature shaft.

Electrolysis :—

Process of Desilverizing Lead by Electrolysis, T. D. Bottome, 442,661. Filed Jan. 2, 1890.

Claim 2 follows :

The process of refining lead containing silver, consisting in electrolytically dissolving the said lead in an electrolytic solution composed of ammonium or synergistic compounds dissolved in water and kept saturated with carbon dioxide, whereby lead carbonate precipitates and silver deposits upon cathodes, substantially as described.

Heating : —

Electric Heater, C. H. Talmage, 442,649. Filed Apr. 11, 1890.

Claim 2 follows :

In an electric heater or converter, the combination of the primary coil surrounding a core of metal strips or wire and a secondary coil of thin sheet metal surrounding the primary coil, whereby the heat produced by the induced current is radiated for heating purposes, substantially as described, and for the purposes set forth.

Electric Cooking Apparatus, E. Abshagen, 442,932. Filed Aug. 4, 1890.

Consists of a closed vessel filled with an oily fluid and provided with suitable cooking compartments heated by the fluid ; the oily fluid is heated through the instrumentality of an electric conductor of considerable resistance immersed in the fluid and in circuit with a generator of electricity.

Electric Steam and Hot-Water Generator, E. Abshagen, 442,933. Filed Aug. 4, 1890.

A closed compartment is located in the boiler or vessel containing the water to be heated ; the closed compartment is filled with an oily fluid in which is immersed an electric conductor, as in No. 442,932, above.

Lamps and Appurtenances :—

Electric Arc Lamp, J. E. Giles, 442,617. Filed Aug. 21, 1889.

Relates to arc lamps for use in series in a circuit of constant potential.

Claim 6 follows :

In an arc lamp, the combination of a gravitative carbon-holder, a rack on the carbon-holder, a fixed train of wheel-work for regulating the feed of the same, the axis of the wheel engaging the rack being movable, a scape-pallet controlled by a regulating-coil for permitting the movement of the train, and a coil in the main circuit for lifting the engaging wheel.

Bracket for Combined Electric and Gas Lighting, J. Gunn, 442,666. Filed March 12, 1890.

The invention consists chiefly in the construction of the joint which enables the bracket to be turned in any desired direction so as to bring the light where it is most needed.

Electric-Light Holder, J. B. Moore, 442,665. Filed June 20, 1890.

A device for attachment to an incandescent electric lamp, by which it may be readily attached to a desk, table, or other support, or placed upon a desk or table in the manner of an ordinary lamp stand.

Pendant Cleat, A. R. Bush, 442,746. Filed June 4, 1890.

Designed especially to be used as a substitute for blocks of the usual rosette form, and particularly intended for use in mills, factories and the like, and especially for high-tension systems.

Portable Electric Lamp, D. G. Fitzgerald and A. H. Hough, 442,969. Filed Sept. 9, 1890.

Especially intended for the use of miners. Includes a case for a battery, and special protection for the lamp bulb.

Claim 1 follows :—

In portable electric lamps, a vessel containing or constituting the cell or cells inclosed in an outer casing, between which casing and the said vessel is interposed elastic material, substantially as herein before explained.

Electric Cut-Out, D. J. Cartwright and J. S. Potter, 443,068. Filed July 14, 1890.

For use with incandescent electric lamps. Design and construction to secure ease and convenience in attaching and detaching lamps from their circuits ; and also with a view of preventing water from getting at the internal parts of the cut-out.

Measurement :—

Electric Meter, A. W. Meston, 442,705. Filed July 22, 1890.

The invention consists of three general features, as follows : A device for measuring the quantity or strength of the current, a device for producing a motion of uniform speed, and a device for registering, by means of the two devices first named, the product of the current strength and time.

Claim 1 follows :—

In an electric meter, the combination, with a solenoid and its core and a lever actuated thereby, of a revolving surface having teeth increasing in number along the generating-line of said surface, and gear carried by the lever, said gear arranged to engage with the teeth on said revolving surface, substantially as and for the purposes specified.

Electrical Measuring-Instrument, E. Weston, 442,843. Filed July 1, 1890.

Apparatus for measuring difference of potential in an electrc current established between terminals. The invention embodies a fixed coil, and a movable coil suspended in the field of force of the fixed coil by a filament, the two coils being electrically connected. On establishing a current through the coils the movable coil is deflected to an extent depending upon the difference of potential existing between the terminals of the device, and the amount of deflection is indicated by a needle moving over a suitable scale.

Reversing Key, E. A. Colby, 442,800. Filed Feb. 28, 1890.

A reversing key adapted for use in a measuring instrument such as that patented to Edward Weston, Nov. 6, 1888. (Letters patent No. 392,387.) Through the combination of the key with the above mentioned instrument the current can be reversed through the rotating coil of the voltmeter without affecting a corresponding reversal of the current through a fixed resistance coil also contained in the Weston voltmeter.

Metallurgical :—

Magnetic Ore-Separator, G. S. Finney, 443,042. Filed March 25, 1890.

The magnetic wheel of the separator comprises a series of electro-magnets having a common core and having the poles extended from opposite ends of the series cross-wise of the plane of the wheel's circumference and forming elements of the wheel's circumference.

Magnetic Separator, G. S. Finney, 443,043. Filed March 25, 1890.

The magnetic wheel of the separator comprises a series of magnets on a common rotary core and alternating as to their polarity ; each magnet has its poles extended continuously around the plane of the wheel's circumference and forms an element of its cylindrical surface. A non-magnetic endless belt surrounds the wheel and affords a support and conveyor for the material to be treated.

Magnetic Ore-Separator, G. S. Finney, 443,044. Filed March 25, 1890.

The magnetic wheel of the separator comprises a rotary shaft provided with heads, and permanently magnetic bars extending lengthwise between the heads, alternating in polarity around the wheel, and forming elements of its cylindrical surface.

Metal Working :—

Method of Welding Metals Electrically, C. L. Coffin, 442,954. Filed June 9, 1890.

The bars, rods, or other articles to be welded together are not placed directly in contact with each other while the heating current is passed through them, but the ends to be welded are in contact with a conductor of similar or less resistance. The first claim describes the method as consisting in connecting each article with one pole of a generator of electricity, making contact between the ends to be welded and an electric conductor of equal or less resistance, passing a heating current through the articles and said conductor, and completing the weld by pressure.

Miscellaneous :—

Automatic Recording Apparatus for Vehicles, J. Bellussich, 442,849. Filed July 11, 1889.

Apparatus for recording the running time of a vehicle and also for recording the time of occupancy by a passenger. The circuit-closer for the electro-magnetic apparatus operating the running-time record is controlled by the motion of the vehicle, while the circuit-closer for the device operating the record of the time of occupancy is controlled by the passenger on taking his seat.

System for Indicating Thermometric Records, H. J. Haight, 442,880. Filed May 3, 1888.

Apparatus to enable a single operator at a main station or observatory to transmit simultaneously by electric means to a series of sub-stations indications which are received or known at the main station and automatically to indicate such indications at the several sub-stations without the necessity of the presence of attendants at the sub-stations when the indications arrive.

Electric Switch, J. O'Brien, 442,996. Filed Aug. 28, 1890.

The object of the invention is to provide a switch by means of which a break or disturbance occurring on a telephone circuit, or other similar circuit, can be corrected as soon as the cause is detected. The invention consists in a novel arrangement of circuit-connections and switch-levers.

Method of Protecting Buildings from Lightning, N. D. C. Hodges, 443,048. Filed Sept. 28, 1889.

Consists, first, in receiving atmospheric electricity as it collects in the vicinity of a building upon a conducting surface ; second, in diffusing the collected electricity upon a large surface of finely divided badly-conducting substance; third, scattering the badly-conducting substance, and so reducing the charge, and, lastly, in conducting the residue of the charge to the ground.

Railways and Appliances :—

Station Indicator, Louis Casper, 442,610. Filed Sept. 12, 1888.

Apparatus, including electro-magnetic devices, for indicating streets or stations upon a railway as they are reached by a car.

Claim 2 follows :

In a station-indicator, the combination, with two electro-magnets and an armature pivoted to swing between them, angular pawls pivoted to the upper end of the armature, a shaft, two ratchet-wheels on said shaft, a roller on said shaft, and a band secured to said shaft and bearing the station names, substantially as herein shown and described,

Electric Trolley Switch and Trip, R. C. Hopson, 442,623. Filed May 5, 1890.

A line switch and junction-trip for overhead railway conductors.

When it is not desired to switch a passing car from the main line, a "trip" that may be provided upon the trolley engages a hanger extending below the switch-plate and jumps the trolley over the switch and back upon the main trolley wire.

Storage-Battery Electric Car, J. Stephenson, 442,744. Filed Aug. 2, 1890.

Design and construction of car, adapted to facilitate the renewal or removal and replacement of storage battery cells.

Claims 1 and 2 follow :

1. A car with foot-panel hinged at its lower verge and with a guard-rail

arranged to support the panel in a horizontal position with supports from the car-body sill, substantially as and for the purpose described.

2. A car with its foot-panel hinged at its lower verge, and a series of locks at the opposite verge of the panel, the bolts of each lock connected with a lock-opening sliding bar, substantially as described.

Train-Telephone, R. S. Carr, 442,799. Filed Feb. 17, 1890.

An intercommunicating telephone service for railway trains. The telephones are pneumatic and are connected together through the medium of tubes containing air under pressure.

Safety Device for Overhead Conductors, R. A. Morgan, Jr. 442,816. Filed March 14, 1890.

The safety-device or switch is made of two or more parts or members, so constructed and adapted as to secure, by means of a spring or a spring-actuated member, a separation of parts adequate to preclude the formation of an arc when contact is broken.

Trolley Line Switch, W. M. Rumsey, 443,004. Filed Aug. 7, 1890.

An adjustable switch for overhead railway conductors.

Consists of an annular base plate provided with a series of slots and a clamping disc; the switch bars, attached between a base plate and clamping plate are adapted to be adjusted toward or away from each other, so that a cross over of any desired angle may be formed.

Trolley-Line Insulator, W. M. Ramsey, 443,005. Filed Aug. 7, 1890.

Consists of a bracket having a tapering circular opening formed therein and upwardly extending hooks, a cylindrical block confined in the circular opening, a bolt secured in the block, and a shoe or clamp attached to the bolt.

Magnetic Shield for Electric Motors, C. J. Van Depoele, 443,019. Filed Aug. 4, 1887.

Designed for the protection of the contents, including the passengers and their watches, of an electric railway car from the magnetizing effects of the lines of force from the field magnet of the motor. Consists of a sheet-casing constituting a magnetic shield permanently interposed between the motor and the interior of the vehicle.

Electric Signaling Device for Moving Vehicles, O. J. Depp and S. J. Munn, 443,074. Filed Aug. 4, 1890.

Claim 1 follows:

An electric signaling device for moving vehicles, consisting of a circuit controlling device located within the brake or switch handle of a car, an electric bell located on the said vehicle, a three line-circuit connecting the said bell with the said circuit-controlling device, and means whereby electricity is supplied to the said wires from the trolley or main line, substantially as described.

Trolley-Switch for Electric Railways, J. Jones, 443,081. Filed Sept. 25, 1890.

Especially adapted to single-track roads where the cars are side-tracked at certain points. The device embodies two movable sections of the conductor, one in the main line and the other in the branch, the sections being held in their normal position by gravity.

Telegraphs:—

System of Telegraphic and Telephonic Exchange, J. R. Smith and W. Childs, 442,784. Filed Sept. 27, 1889.

The object is to provide an exchange system whereby connections and disconnections may be effected at the central office by the operator at a local station promptly, secretly, and automatically.

Claim 4 follows:

A system of telegraph or telephone exchange having a switch-board in which circuit-wires terminate, an electrode-coupler attached to a movable belt supported and operated by one or more wheels, said belt and one of said wheels being in electrical connection in the circuit, and an electro-magnetic propelling device in a line from one of the stations in connection with said wheels to move said electrode-coupler into electrical connection with any and all of the circuits so terminating.

Telegraphy, A. G. Hummel and F. A. Graham, 442,808. Filed July 10, 1890.

Intended to provide a system especially adapted for rapid sending in the police or the railway service. For security and the detection of error provision is made for the printing of all messages, whether general orders or of whatever character, at both the transmitting and the receiving station.

Telephones and Apparatus:—

Means for Reducing Inductive Disturbances in Telephone-Circuits, J. J. Carty, 442,856. Filed Sept. 18, 1890.

An electrically symmetrical arrangement and interconnection of circuits adapted to distribute inductive disturbance in such wise as to neutralize its effect upon the telephone circuit, so arranged and interconnected.

Claim 1 follows:

Three or more metallic electric circuits extending parallel to each other, as described, combined with means such as the lateral branches or condensers, connected with the central circuit and extended along the more distant conductor of the side circuits, as specified herein, whereby each conductor of the said central circuit is enabled to exercise equal and like electrostatic inductive effects upon both near and distant conductors of its adjacent side circuits, for the purposes set forth.

Combined Electric Indicating and Telephone System, H. J. Haight, 442,883. Filed May 9, 1890.

The invention combines with an indicating system—such as a stock-quoting system, or the distribution of meteorological indications and the like—means for signaling or communicating between the various stations for other purposes than the transmission of the usual indications for which the system is established, and provides also a telephone system as part of the combination.

THE ELECTRIC RAILWAY FIGHT IN ORANGE, N. J.

At the meeting of the Orange Common Council on December 15, the statement was made by F. W. Kelsey, one of the opponents of the proposed electric railroad on Central avenue, that by January 1 he and some of his friends would be prepared to pay for a franchise provided the road was located south of Central avenue or parallel with that thoroughfare. Such a road would open up new territory and give the rapid transit needed without spoiling Central avenue, which is now devoted to dwellings, and is practically the only road on which it is possible to drive safely between Newark and the Orange mountains. In view of that statement the consideration of the ordinance by which the Aldermen proposed to grant the application of the Suburban Rapid Transit Company for a franchise for a railroad on Central avenue for a small consideration was laid over until the regular meeting in January.

LEGAL NOTES.

THE GOVERNMENT vs. WESTERN UNION—TO RECOVER $12,495 PAID FOR MESSAGES.

Before Judge Lacombe and a struck jury, in the United States Circuit Court, this city, trial was begun last week in a case in which the Government sues the Western Union Company and the Union Pacific Railroad Company, to recover $12,495.62. This is the amount paid to the Western Union for telegraphic messages sent by various departments of the Federal Government, over lines of wires extending from the Missouri River to San Francisco since 1881. The United States District Attorney, J. W. Mitchell, in presenting the case, stated that the acts of Congress under which the Central Pacific Road was organized, and the amendatory acts thereto, provided that the Government should be entitled to retain all fixed charges for Government telegraphic despatches, and apply the same to the payment of the bonded indebtedness of the road; and that all the earnings of the road, both for the transmission of freight and passengers and of telegraphic messages, 5 per cent. should be paid into the United States Treasury. The telegraph lines formerly operated by the Union Pacific Roads were surrendered to the Western Union by an agreement entered into in 1881, since which time the Government has had to pay for all its telegraphic messages. The further claim is made that by this surrender of the telegraph system of the road the 5 per cent. of the earnings of the Union Pacific to which the Government is entitled is diminished.

G. A. HALSEY vs. NEWARK RAPID TRANSIT RAILWAY CO.—POLES MAY BE PLACED ON A STREET.

Mr. Halsey's application was to have the Chancery Court enjoin the company and thus require it to remove the poles used by its electric road in front of Mr. Halsey's property. The poles are in the middle of the streets. Mr. Halsey's title runs, like most others, to the middle of the street, and he claimed that the poles infringed upon his property, and that such use of the street was not authorized by the laws regulating highways.

The Vice Chancellor, Van Fleet, denies the injunction, and the following points cover the main features of his interesting and forcible opinion. He declares:

That the complainant (Mr. Halsey) has a fee in the land occupied by the street, but this is subject to the public easement, or right of way.

That the fee when subject to such easement is of no beneficial interest to the holder.

That the public right to free passage over the land which is now used as a highway, not only means such methods of conveyance as were in use when the highway was laid out, but all improved means.

That since horse railroads have been decided to be a legitimate use of the highway, an improved plan of transportation must certainly be considered a legitimate use.

That the poles and wires have been placed in the street to aid the public in exercising their right of easy and rapid passage over the street.

That the company is legally organized under the street railroad law of 1886; that the law permitting the use of electricity as a motive power is in strict accordance with the first act, and that the State laws and municipal authority cover together the case completely and legalize the erection of the poles.

That the poles and overhead wires are a portion of the best, if not the only means, by which electricity can be successfully used for street car propulsion.

That the city's consent by resolution instead of ordinance was legal and sufficient.

That it is consistent with street uses that the authorities should adopt "the improvements and conveniencies of the age."

That the pole in front of Mr. Halsey's japannery forms no real obstacle to entrance to the yard.

That the electric current used by the company may be used with entire safety to everybody.

THE DENVER, COL., ELECTRIC LIGHTING CONTRACT VOID.

An important decision has been rendered by Judge Allen, in the case of Tabor et al. vs. The City of Denver and the Western Electrical Construction Company. A short time ago the city entered into a contract with the above company to furnish lights to the city for a specified time. Later suit was brought in the name of a number of prominent citizens and taxpayers to set aside the contract. The decision is in favor of the plaintiffs. Judge Allen holds that neither the city council nor any officials of the city had the power to make such contract, and that the ordinance making the contract, as well as the contract itself shall be void.

FINANCIAL MARKET.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of December 20, from New York, Boston and Washington; Pittsburgh, December 19.

"TWO-AND-A-HALF-MILES-A-MINUTE."

Under the above title a lecture was delivered at the Franklin Institute on Dec. 16, by Prof. W. D. Marks. In the course of his lecture, which was extemporaneous, he described the overhead system, which "is now in possession of Boston," as an intolerable nuisance. Wires are being stretched everywhere over the city at a height of only 18 feet above the streets, and, aside from this practical inconvenience, there is the constant danger to pedestrians from breaking or falling wires. The company claims to carry a current of but 500 volts, but Prof. Marks said that, from his observation, it was often very much above 500. As to the storage battery car, he said there could be little doubt a battery would ultimately be perfected which would serve the purpose, but that it is not likely that it will prove as cheap as the use of the direct current. The storage plan, he thought, was cheaper than horses, but the dynamo will beat the storage battery. As to the underground conduit plan, he thought one could be devised which would be easily accessible for repairs and would not cost over $30,000 a mile, while the power ought to be produced at a cost of not over five cents per horse-power per hour, including all clerical and administrative expenses.

The lecturer touched briefly also, upon the elevated and underground systems of rapid transit, holding, with reference to the former, that there was no reason why the elevated railway should be made such a horror as it is in New York. Different methods of construction and the use of electric motors would obviate much of the present annoyance. With reference to the high speeds of which he had spoken Prof. Marks said that they could only be attained by electricity, and that it would involve essential changes in road bed, rolling stock, etc. After pointing out the advantages of a system of electric motors, Prof. Marks said he would not hesitate personally to drive a motor from Philadelphia to New York at the high speed he had named—2½ miles a minute.

FRANK KITTON ON ELECTRIC TRACTION IN BUFFALO.

"The Advance of Electric Traction," was the title of an interesting paper read before the Buffalo Electrical Society last week by Mr. Frank Kitton of the Western Union. He said that less than two years ago he had addressed the Society on the same subject, and at that time had predicted that public prejudice against the use of the trolley system in Buffalo would give way before the necessity for a better street-car service, and that electric motors would eventually displace horse power as an agent in operating street-cars. After speaking of the opposition encountered by the Street Railway company in obtaining the necessary permission to make the change, Mr. Kitton said that the danger which at that time was so much apprehended from the introduction of electricity did not appear to agitate the public mind so much as the question so often asked, and so seldom satisfactorily answered, When will the electric cars commence running? From the statistics gathered up to date there were, it appeared, no fewer than 246 electric roads in this country, operating 2,024 miles of track and employing 3,830 motor cars, the single trolley system, with only a few exceptions, being that in general use. Mr. Kitton then described the various systems.

TRADE NOTES AND NOVELTIES
AND MECHANICAL DEPARTMENT.

NEW CATALOGUE OF ELECTRIC STREET RAILWAY SUPPLIES.

The Electric Merchandise Co., 11 Adams street, Chicago, Ill., now so widely known as dealers in electric street railway supplies of all kinds for all systems, are busily engaged in preparing a "mammoth new catalogue" of everything in this line heretofore on the market and also of many new and highly valuable devices and specialties. It will be profusely illustrated with handsome cuts and each article described clearly and will be ready very shortly. This valuable book should be in the hands of every electric street railway man in the country, and all should write for a copy without delay, as it will form a perfect "encyclopedia" of electric railway work, and everything pertaining to this branch of electrical work will be contained therein. Mr. Mason, the manager of the company, is having an extra large edition prepared to meet the large demand, as he intends sending it broadcast everywhere and expects to receive applications for a copy from everyone interested, as it will be something entirely novel in its completeness and scope.

ELECTRICAL PRODUCTS OF THE REVERE RUBBER CO.

The production of numerous substitutes for hard and soft rubber, as used in electrical apparatus, has only tended to increase the variety of forms in which this may become a part of various appliances. The strength and firmness of the hard rubber, the elasticity of the soft, together with the durability and high insulating qualities of both have given them a well-earned foothold. Moreover the process of manufacture has been perfected, so that with the aid of specially designed moulds and tools, rubber pieces of high quality can be made at a comparatively low price. The variety of sizes and shapes in which the rubber parts can be made is almost endless and serves to adopt this material for use in a large range of electric appliances. The design of pieces for such uses properly comes within the sphere of the consulting electrician, and yet the rubber manufacturers have generally undertaken this work. Accordingly, the Revere Rubber Co. has established an electrical department, which will not only furnish rubber pieces as now in common use, but will also be prepared to design special fittings to meet any special conditions.

The Western agency of this department is in the hands of Mr. George Cutter, whose long and varied experience in electrical work would seem to fit him specially for this position. The Revere Rubber Co. has a well-established reputation as a maker of a high grade of rubber goods, and its placing this department in the hands of so practical an electrician as Mr. Cutter will be welcomed as a decided step forward.

A NEW ELECTRIC RAILWAY SWITCH.

Messrs. Charles W. Smith and Cornelius J. Lyons, of Boston, are the inventors of an electric switch to be used where the electric system is in operation on street railways. The West End Street Railway Company has a model of the invention, and may give it a trial before long. The switch appears to be a practical one and very easy in its action.

THE SHAVER MOLECULAR TELEPHONE.

The Shaver telephone has just been successfully introduced in Skowhegan, Me., and it is said that a number of business men will introduce it and push its interests.

HUNT ENGINEERING CO.

A fine installation has just been completed by the Hunt Engineering Co., in the electrical plant for the new theatre at Norwich, Conn. A very fine switchboard of slate, cased in a frame of solid carved English black oak has been put in, on the stage, with subsidiary switching arrangements in other parts of the house. There are also special devices for turning the lights down when soft effects are required, and moonlight or sunset effects are obtained very successfully. Okonite wire is used for the circuits. The plant started off at once smoothly and easily, and the local press speaks most highly of the Hunt Company's work.

ACTIVITY OF THE ELEKTRON CO.

The Elektron Mfg. Co. have recently sold to Messrs Warfel & Geist, of Lancaster, Pa., 30 h. p, in Perret electric motors. These machines will be supplied with current by the Edison Electric Illuminating Co., of Lancaster, and will furnish power for all the machinery in the large brick building recently completed by Messrs. Warfel & Geist, including large Hoe presses for printing the daily and weekly *New Era*, as well as all the job presses, which go to make up one of the best and largest printing establishments in the State. Messrs. W. & G. have had experience with several other motors, but after a thorough investigation and a visit to Brooklyn and New York, where they witnessed the motors in operation, placed their contract for Perret machines.

The following is a sample of the testimonials now being received by The Elektron Mfg. Co.

MINNEAPOLIS, MINN., Dec. 3rd, 1890.

MR. F. J. RENZ, Agent.

Dear Sir :—In reply to yours of the 3rd in regard to testimonials will say that I am so well pleased with the Perret Motor in *all respects* that I will permit your people to write anything they see fit over my name, providing it is *all in favor* of the PERRET, and will do all I can in any way to help you in Minneapolis. Yours respectfully,

F. G. WARD, Mgr.,
The Great Atlantic & Pacific Tea Co.

THE ANDERSON TROLLEY POLE.

ONE of the most important necessities of a good overhead trolley system for electric railroads is the trolley pole, and many forms of pole have been used with varying success. Wood, gas pipe, iron pipe, seamless steel tubing with three or more joints have all been tried. Probably the most successful and durable has been the seamless steel tube but the necessity of making the pole in lengths, so as to gradually give it a taper appearance, has proved a drawback. To remedy this defect Messrs. A. M. and J. Anderson, of 21 Hamilton street, Boston, have just brought out a new pole which is made in one piece of soft steel and is gradually and evenly tapered down from the butt to the point. It is neat and light and is at the same time extremely strong and durable, being made of the very best material. The pole will stand a very heavy strain and is so tough that it can be doubled and then straightened out again without in any way destroying the material. A number of these poles are already in service on the West End Street Railway, of Boston, and electric street railways would do well to give them a trial.

THE ANDERSON TROLLEY POLE.

CHANGES IN WESTINGHOUSE MANAGEMENT.

A paragraph from Pittsburgh of Dec. 15, says: "The *Leader* is now in a position to state on authority entirely trustworthy that the changes in the Westinghouse Electric Company management outlined in the Saturday issue will be made. General Manager Byllesby will retire to make way for Mr. A. M. Byers. Assistant Treasurer McCullough will also retire, but as yet his successor has not been announced. The banks in interest here decided to advance the money asked for, and only minor details are to be looked after before the deal is closed. This will put the electric company—certainly a money-making concern when properly managed—on a sound footing and it would seem that the improvement noted in the stock to-day reflects these changes."

W. H. GORDON & CO.

W. H. Gordon & Co., 115 Broadway, report large sales of the Star Electrix specialties, for which they are general selling agents. The sockets especially have been in large demand and orders are booked way ahead for future delivery. They are now fully stocked with the switches and cut-outs and can fill orders promptly.

These goods are not only mechanically well made but are also artistic in appearance and electrically the best ever offered on the market.

THE C. & C. "BLOWER" ON THE "BALTIMORE."

The C. & C. Electric Motor Co. less than twelve months ago manufactured the first of its blower and motor combinations with which most people versed in electrical appliances are now familiar. This apparatus was primarily designed for use in dynamo and engine rooms of steamers and in other places where it is essential to produce a rapid and thorough ventilation and where the space is circumscribed. Owing to the extreme compactness of the machine it may be placed in the smallest room and proves a most powerful exhaust. The apparatus was first used on the U. S. S. "Baltimore" and Capt. Schley commanding that ship declared in a letter written to the "C. & C." Co. that it gave "perfect satisfaction." The installation on the "Baltimore" has been followed by others on the "Chicago," "Charleston" and "Petrel," and three more blower combinations are now under construction by the "C. & C." Company for others of our new cruisers. The Italian Navy not to be left behind ordered two of these blowers some few months ago and after giving the apparatus a thorough test have recently, through their agents in Milan, placed a further order with the "C. & C." Company, for nine, including six of the No. 7, or largest size machines.

GIBBON DUPLEX STREET RAILWAY TRACKS.

An interesting pamphlet has been issued from the Gibbon offices, No. 1 Broadway, New York, relative to the Gibbon duplex street railway tracks recently illustrated and described in our columns. The pamplet abounds in cuts showing the various features of this excellent and economical system, and there is some very pithy descriptive matter as well as pertinent argument on the subject. For their own sakes, electric railway men should look into this method of track construction.

ELECTRIC RAILWAY WORK AT JAMESTOWN, N. Y.

The Jamestown Street Railway Co. has contracted with the Short Electric Railway Co. for complete electrical equipment, including twenty 15 h. p. motors and ten car equipments, three 80,000 watt generators, and line construction for about 12 miles of track. The contract was awarded to Mr. T. C. Frenyear, who represented the Short Co. at Jamestown, after very sharp competition. The apparatus ordered is sufficient to provide for the new line to Lakewood on Chautauqua Lake. It is expected that the road will be in operation by May 15th. The installation will be a notable one, inasmuch as the grades are numerous and heavy, there being three of more than 9 per cent. The power station will be a model one in every respect, and large enough to accommodate eight 110 h. p. generators. It is situated on two railroads and the Chautauqua Lake outlet, so there will be no handling of coal, and water for condensing purposes will be abundant.

ELECTRICAL TRANSMISSION OF WATER-POWER.

The Gray Current Motor Co., of Elgin, Ills., has, through the efforts of Capt. C. F. Dunderdale, of the Rookery Building, Chicago, secured the large water power at Oregon, Ills., and will at an early date install a large power plant there, consisting of a large flume to be built to take the flow of the Rock River, and in this flume will be placed the Gray current motors, which will deliver their power to large electric generators, and which in turn will, through the medium of cables, distribute the power to manufacturing establishments in the town operating by electric motors.

It is the intention of the Gray Co. to install a plant of a capacity to deliver some three thousand horse power of electrical energy in the town and make available for manufacturing sites large parcels of land hitherto too distant from the waterfall to be of value. This will give a great boom to the town and made it sought after by manufacturing concerns looking after an elegible site for a permanent place of location.

Since natural gas has shown itself so unreliable, water-power sites are much desired, but unfortunately there are but few near Chicago, and those few are already overloaded.

The engineering work will be under the direction of Capt. Dunderdale, who is well versed in all the details appertaining thereto, and has had large experience in this kind of work. His enterprise will create a new era in the prosperity of the town, and the example set will doubtless be followed in other places, as many inquiries are already pouring in to him from various points where the people are desirous of having a similar establishment erected and increased power from their waterfalls obtained for local requirements.

MR. O. T. CROSBY, the manager of the Southern District of the Edison General Electric Co., has resigned, and has proceeded from New Orleans to Boston, where he assumes new duties in the Thomson-Houston Electric Co., associated with Capt. Eugene Griffin.

THE FORT WAYNE ELECTRIC COMPANY have just taken an order for a 1,200 light alternating equipment for the Morristown, N. J., Electric Light, Heat & Power Co.

McCREARY'S MOISTURE-PROOF SOCKET PROTECTORS.

INCANDESCENT lamps are frequently placed out doors and where this is the case means must be provided for preventing the entrance of moisture into the socket which would cause leakage or even a short circuit. Rubber envelopes have heretofore been

McCREARY'S MOISTURE PROOF SOCKET.

provided for the sockets in such cases, but experience has shown that they harden and crack and frequently require a new one every time the lamp is changed ; and in addition they require the removal of the socket to adjust them.

To obviate this difficulty the McCreary Electrical Specialty Co., of this city, has brought out the socket protector illustrated in the accompanying engraving. As will be seen, it consists of a metal cap A containing a rubber gasket. The socket is enclosed in a metal shell B, the opening where the lamp is inserted being covered by a rubber neck C. By this construction the renewal of a lamp requires only the removal of the rubber neck C, which is as easily adjusted as the lamp. The extremely low cost of the rubber neck makes the use of this device very economical.

The McCreary socket evidently obviates the necessity of glass globes for outdoor incandescent lamps, which not only obstruct considerable part of the light, but are expensive and liable to breakage.

THE F. & M. DEPT., HARRISBURG CAR MFG. CO.

While most people are aware that this company is still turning out Ide and Ideal engines to the utmost capacity of its shops, still the impression seems to be current that the foundry and machine department is crippled badly by the recent failure of the Harrisburg Car Mfg. Co., whose affairs are now in the hands of a receiver.

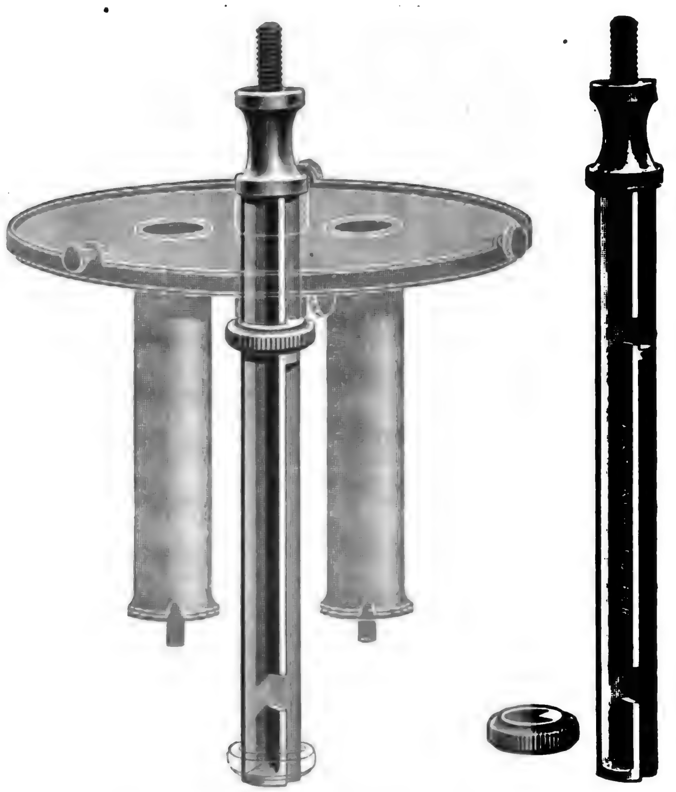
The business of the " F. & M." Department is, in fact, better than ever, and in order to give its functions more scope, it will soon be reorganized as a separate and distinct company with a large working capital. In the meantime John Post & Co., of Boston, and W. R. Fleming & Co., of New York, agents, keep the Harrisburg people busy filling orders.

The accounts of the F. & M. Department will, we are informed, positively be paid in full.

THOMSON-HOUSTON PLANTS.—The Western Isolated Department of the Thomson-Houston Electric Co. have received orders from the Bi-Metallic Mining Co., of St. Louis, for 200 incandescent lights ; the Albert Dickinson Seed Co., Chicago, for 100 incandescents, and G. B. Lewis & Co., Watertown, Wis., for 100 incandescents.

CUTTER'S GLOBE HOLDER FOR ARC LAMPS.

In trimming arc lamps, much time is often lost either because the globe is fixed and in the way, or because the arrangement for slipping it down while the carbons are being renewed is imperfect. Thus in the case of the Thomson-Houston double carbon lamps, the globe-holder slides on a brass tube and is held in place by a screw pressing against this tube. To insure the grip of the screw, the trimmers will often use their pliers on it, and in a short time the tube becomes indented or even split, the screw is bent and sticks, and the ring no longer slides freely. All this causes a loss of time in trimming the lamp and does not tend to improve the good humor of the trimmer. As a simple substitute for this bothersome arrangement, George Cutter, of Chicago, has brought out the device illustrated above. As the cuts show, a rod with a star-shaped cross-section is used instead of the tube, while the screw is replaced by a ring which is adapted to engage the rod at two points. When in use the globe-holder proper rests on this ring, which is knurled so as to be readily turned with the fingers. A slight raising and turning of the ring allows it to drop to the end of the rod, thus lowering the globe out of the way. After the lamp is trimmed, the ring is raised again and a quarter turn brings it back to its original position, where it supports the globe-holder securely. To remove this entirely, the ring is slipped down until opposite the lower notch in the rod, where both the ring and the globe holder can be taken off together. The globe can then be replaced and the holder slipped back and clamped in place in an instant. Thus, it takes but a moment to lower the globe where it will be out of the way, to raise it again into position, or to remove



CUTTER'S GLOBE HOLDER FOR ARC LAMPS.

it altogether. Such a labor saving device ought to pay for itself in a short time, and as it is simple and well made it may even outlast the rest of the lamp. As it fits any Thomson-Houston double carbon lamp, it will find a ready market wherever these are used. George Cutter is pushing this device from his office at 833 "The Rookery," Chicago.

ELECTRICAL SUPPLY CO., CHICAGO.

Mr. M. M. Wood is now with the Electrical Supply Co., of Chicago, in their engineering department, having severed his connection with the General Edison Electric Co., Portland, Ore., as district electrical engineeer.

THE EUREKA TEMPERED COPPER CO., of North East, Pa., report shipments for October and November of their tempered copper goods in excess of any amount previously shipped in any other four months since they began business.

DALLAS, TEX.--The Dallas Electric Co. will issue $300,000 of bonds for the purpose of improving its electric light plant.

GREAT WESTERN ELECTRIC SUPPLY CO.

The above-named house are doing a phenomenally large business in general electrical supplies of classes and orders are pouring in from all over the country. The demand for Simplex wire, carbons, porcelain and glass specialties and fixture, are unprecedented in the history of the house.

"DAISY CHAIRS" ON THE NEWTON, MASS., ELECTRIC RAILWAY.

Mr. R. T. White is in receipt of the following from F. G. L. Henderson, superintendent of the Newton Street Railway Co., which is running heavy electric cars over its lines: "We have recently laid in Newton and Waltham, five and one-half miles of track, more than three of which are laid on your chairs, and since they have been in use, they have given perfect satisfaction.

"When laying track in Newton, we gave them a severe test, by running a seventeen ton steam roller over our road bed, first filling it in with ten inches of crushed rock. We found no evidence of any failure to hold this immense weight and consequently I have full confidence, that if the material of which it is made, is kept up to the proper standard, your chair will do all that you claim for it.

"I see no reason why it should not meet with the approval of street railway managers who will give it a trial, as its low price and durability are points which surely ought to commend it to them."

AN IMMENSE STOCK.

The Great Western Electric Supply Company, 190–192 Fifth avenue, have got their five-story and basement building filled from roof to cellar with all kinds of the choicest electrical supplies and are carrying, it is said, probably the largest stock of any supply company in the country, that at present on hand aggregating over $250,000 in value.

NEW ENGLAND TRADE NOTES.

The Standard Electric Co., of Vermont, have sold a 200 light plant to the East Shore Terminal Co., of Charleston, S. C., and a 50 light plant to the Beaver Mills Co., Keene, N. H.

H. N. Bates & Co., of Boston, have secured the order to furnish the shafting, pulleys and friction couplings for the Johnstown Electric Light & Power Co., of Johnstown, N. Y. The order calls for 12 pulleys, and Hunter friction couplings for about 600 h. p. and about 200 fe t of shafting. This plant will be made a model plant as regards the shafting arrangements, no expense being spared to make it complete. The bearings will be on special frames, and the shafting of special forged steel.

Pettingell-Andrews Co.—The Boston stock exchange has admitted for dealings in the unlisted department the Pettingell-Andrews Company, which is engaged in the electric light and railway supply business; capital, $200,000, in 8,000 shares of $25 par value. The officers are: F. E. Pettingell, president; D. A. Andrews, Jr., vice-president; D. A. Andrews, treasurer; C. B. Price, secretary; and they, with Ambrose Eastman, are its directors. The business of the Pettingell-Andrews Company has been steadily increasing throughout the past year, and they have just declared a semi-annual dividend of 5 per cent. payable on December 1st. They have just been appointed exclusive New England agents for the well known Paiste switches. Mr. F. E. Pettingell has just returned from Chicago and the West, where he reports business as extremely brisk in their specialties. Mr. D. A. Andrews, Jr., has just made a complete tour of the South, going as far as New Orleans, and secured good business, while Mr. Levi Cofren, their popular agent in New England, has been pulling in good orders in Okonite and other line wires. The K. W. specialties continue to take the market, while the sales for the S. S. Key and Keyless socket has been something unprecedented, over 100,000 being already in use. In my article on the new Worcester station in our issue of December 16th, it should be added that all the wire used in the station was Okonite, and the Pettingell-Andrews Company have been making a specialty of this class of inside station work for some time.

The Economic Electric Manufacturing Co., of Brockton, Mass, are rapidly achieving success with their new incandescent lamps, and are building up a nice business. After January 1st they will have a capacity of 600 lamps a day, and since their commencement in October, they have averaged a manufacture of about 2,000 lamps per week. Amongst recent business, they have received orders from the *New York Herald*, the *Boston Globe*, and the West End Street Railway Co., of Boston. They are also making a specialty of large 75 and 100 c. p. incandescent lamps with double filament which are giving excellent satisfaction.

The Standard Electric Supply Co., of Boston, have just been appointed agents for New England for John A. Roeblings' Sons Company, of Trenton, N. J., representing all wires of their manufacture. They will carry a large stock for immediate shipment of underwriters wire, weatherproof wire, magnet wire, lamp cord, and all sorts of bare wires for telephone and telegraph purposes.

Bridgeport Machine Tool Works, Bridgeport, Conn.—One of the most beautiful illustrated catalogues of machinery which I have ever seen, came to hand recently from the Bridgeport Machine Tool Works, of Bridgeport, of which Mr. E. P. Bullard is the energetic proprietor. The catalogue embraces boxing and turning mills, bolt cutters, chucking machines, compound turrets, lathes of all descriptions, screw machines and tools, shapers, and a host of special machines. The catalogue is neatly printed on very fine paper, is profusely illustrated with the very finest cuts, and is beautifully bound in stiff green cover. It is an ornament to any office, and users of machine tools should at once procure a copy.

WESTERN TRADE NOTES.

The Illinois Electric Material Co., 339–341 Rookey, report continued activity in all branches of their numerous supplies and specialties. They are doing a large and increasing business in poles, and electrical men all over are showing a very strong disposition to have their poles orders accompanied with a good supply of their famous "Canvas-Jacket" line wire to string on them. This wire is meeting with extended adoption by reason of its high insulating qualities, durability and immense resistance to abrasion. They have just taken hold of the various specialties made by the Star Electrix Co., of Philadelphia, and have already booked some nice orders for the same.

The Fort Wayne Electric Co., through their Chicago office, have closed a contract for 740 2,000 candle-power arc lamps of their well-known "Wood" system for Louisville, Ky.

Mr. C. A. Robinson, formerly manager of the Street Railway supply department of the Great Western Electric Supply Co., has joined the forces of the Electric Construction and Repair Co., Springer building, this city, and will handle the many new and valuable electric street railway specialties which this company are now busy manufacturing and will place on the market immediately.

Mr. J. E. Wilson has associated himself with Mr. W. B. Pearson, the Western agent of The Ball Engine Co. of Erie, Pa., and will be located in the Rookery. Mr. Wilson has been for some time past prominently connected with the Western Power Construction Co., and this company having gone out of business, he has seen fit to connect himself with the Ball engine interests. Mr. Wilson has had a long and most extensive experience in mechanical and electrical engineering, having been engaged in this class of business for the past 14 years, and he is a pioneer in many of its branches. He was formerly for a number of years allied with the Bell Telephone Co., of Boston, and later was superintendent of the Financial Telegram Company of that city, which position he filled for five years with the greatest credit to himself and the unbounded satisfaction of the company. When he came West to represent the interests of the McIntosh-Seymour engines, a position for which he was peculiarly fitted by his previous experience, he soon showed his capabilities in this line by the large amount of business which he secured and the number of those excellent engines which he placed. Mr. Pearson and The Ball Engine Co. are to be congratulated on having secured his services, and Mr. Wilson is especially fortunate in being connected with a concern whose engines are so well and widely known.

Mr. D. T. Everts, assistant manager of the Simplex Electrical Co., of Boston, is in town for a short visit.

Mr. G. A. Edward Kohler, Western manager of the Eddy Electric Motor Co., of Windsor, Conn., is going East to Philadelphia for a two-week vacation.

The Electrical Supply Co., of Chicago, is making a special Christmas display of electrical effects and novelties in its Randolph street windows, and it has issued neat little special invitations to its friends to be on hand any evening between 4:30 and 6, to see the show.

Chas. G. Armstrong, some of whose electrical inventions have been illustrated in our columns, has resigned the position of assistant manager for the Great Western Electric Supply Co., and is now turning his attention to contract work. Besides his own devices, he is prepared to install others which have been equally well worked out, and already has contracts under way in some of the largest buildings in Chicago. His wide acquaintance among architects as well as electrical people in the West foretells his success, and his ingenious contrivances will soon find their way into many parts of the country. At present his address is 333 "The Rookery," Chicago.

THE

Electrical Engineer.

VOL. X. DECEMBER 31, 1890. No. 139.

THE INFLUENCE OF POSITION OF COMMUTATION ON THE OUTPUT OF A SHUNT-WOUND DYNAMO WITH SIEMENS "H" ARMATURE.

BY J. MARTIN.

THE dynamo in question is one of a type which has found an extended application in electroplating work, and tests made recently by the writer to determine its capacity at its rated speed of 1,250 revolutions are the basis of the present

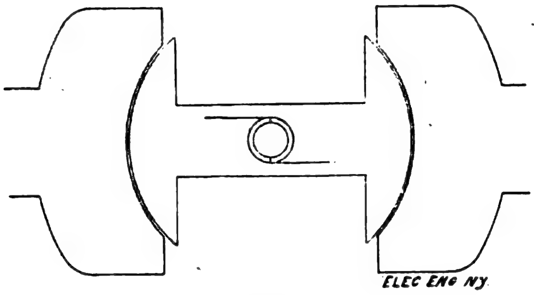


FIG. 1.

article. The field is of the bi-polar type with yoke on top and is made of cast iron, in three pieces.

In the tests the field regulator was short circuited so that

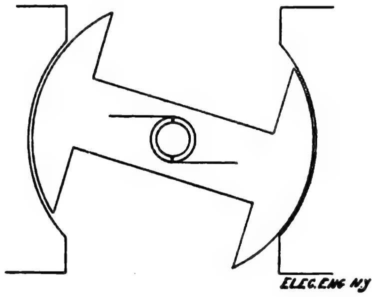

FIG. 2.

the field strength was at all times the maximum attainable under the attendant circumstances. The armature core is composed of twenty-eight wrought iron discs one-eighth of

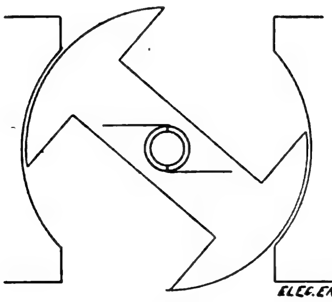

FIG. 3.

an inch thick, with a malleable iron head at each end. The armature winding is in one coil and the commutator has two sections.

In the tests the brushes were fixed in position and the commutator and armature core, which are adjustable relatively to each other, were shifted to the required positions.

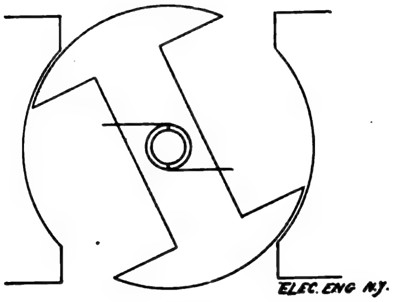

FIG. 4.

In Figs. 1, 2, 3, 4, 5 and 6, the six relative positions of the pole pieces, armature core, commutator and brushes at the time of the brushes leaving one commutator section for the other are shown.

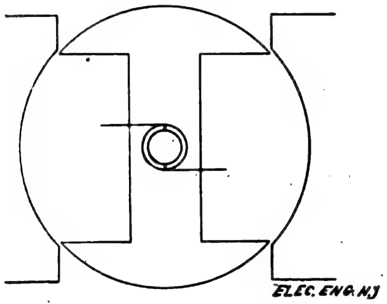

FIG. 5.

Fig. 7 shows the curves (which are numbered according to the positions already shown in Figs. 1 to 6) of the output measured in volts at the binding posts of the dynamo

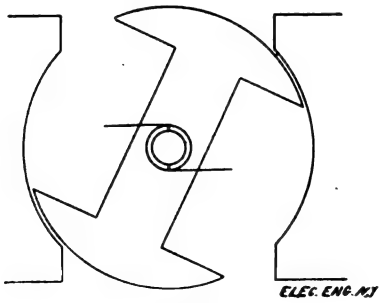

FIG. 6

and amperes in the external circuit, taken on non-inductive resistance.

The curves, 1 R, 2 R, 4 R, are taken on residual magnetism at the positions indicated by their respective numbers. The points on the curves at which the watt output is a maximum is at the centre of the small circles shown. The accompanying table gives the numerical value of this point with the other necessary data.

Position.	Volts at Open Circuit	Speed at same.	Maximum Watts.	Volts at Maximum Watts.	Amperes at Maximum Watts.	Speed.
1	2.08	1,290	39.2	2.8	14	1,290
2	4.3	1,230	71.3	3.1	23	1,240
3	4.32	1,270	89.6	3.2	28	1,260
4	3.65	1,280	102.5	3.04	33.4	1,250
5	2.95	1,290	94.5	2.7	35	1,270
6	.15	1,290				
1 R	2.14	1,320	7	1.4	5	1,320
2 R	3.1	1,320	18.9	2.1	9	1,320
4 R	2.5	1,300	23.4	1.8	13	1,300

As is readily apparent, there is considerable interest attached to the curves on which the following remarks may be made:

Curve 1.—This was taken at the position of theoretical

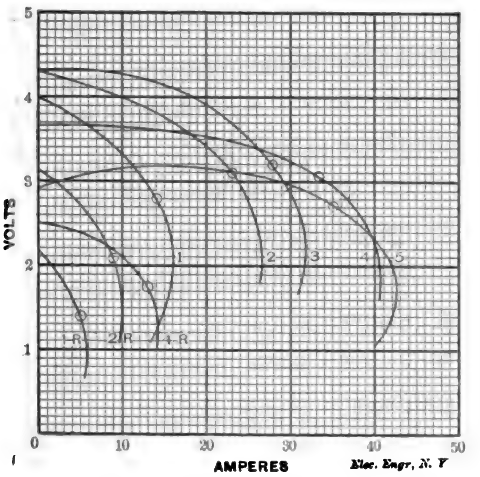

FIG. 7.

commutation. The sparking was excessive at the open circuit reading but decreased as the external current increased, and at 15 amperes was slight. *Curve* 2.—This position nearly coincides with that of highest voltage with

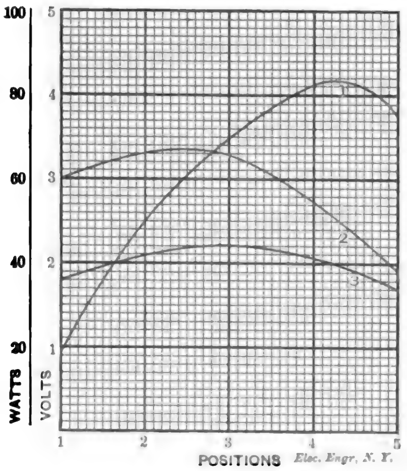

FIG. 8.

a separately excited field and no current flowing in the armature. *Curve* 3.—The sparking was bad at open circuit, followed by a decrease, then increasing and decreasing again to very slight at the maximum current. *Curve* 4.—This curve is specially characterized by an even voltage from 0 to 12 amperes and giving the maximum watt output of the positions tested. The sparking on open circuit was bad; but from 10 amperes to the maximum was slight. *Curve* 5.—We have here the very interesting feature of a decided rise in voltage with current up to 15 amperes dropping even with the initial at 29.5 amperes, at which point the speed had decreased 20 revolutions. The maximum watt output is less than in the preceding position. The sparking was slight at open circuit and was 0 over almost the entire range of current. Position 6 gave .15 volts negative on open circuit, and no further readings were taken on it.

With the idea of possibly getting a more positive effect of the action of the current in the armature, the curves 1 R, 2 R, 4 R, were taken after charging the field for each to the maximum extent obtainable from its own current.

The curves present the same general characteristics as those obtained with the field self-excited at the same positions.

To get an idea of the relative effect of the various positions tested, the curves shown in Fig. 8 were plotted taking positions as abscissas and maximum watts (Curve 1), open circuit volts (Curve 2), and volts at maximum watts (Curve 3) as ordinates.

The maximum positions are for watts, between positions 4 and 5, nearest 4; open circuit volts, between positions 2 and 3; volts at maximum watts at position 3.

THE "THRILL OVER THE WIRE."

BY PATRICK B. DELANY.

I HAVE recently been asked for my opinion on the "thrill over the wire" subject which has been discussed so actively and considerably in the newspapers. My recollection of the cause of this discussion is that a telegrapher relates an experience which he is unable to account for, to the effect that in the performance of his daily work of sending and receiving messages, he has experienced a peculiar "thrill" when working with a certain operator, while his work with the rank and file has been unattended by this pleasing sensation, and, that although this operator who thrilled him was not himself much of an artist in his line, still, whenever he worked the key at the other end, the relator was in a measure put under a spell. Moreover, on one occasion when almost incapacitated for work by illness, the call of this particular operator from the other end of the line infused in him a mysterious vitality which drew him from a sick couch to the instrument and held him there in the performance of his duty until his malady left him. Other operators have come forward and expressed themselves as having been similarly affected by certain affinities or controlling influences over the wires, and without attempting any explanation they simply allege or admit that they have felt the "thrill."

Speculation as to the nature of this mysterious influence runs mainly in the direction of hypnotism, and the question is asked whether or not the hypnotic influence can be sent electrically, or exerted over a wire just as well as though the parties were face to face. In affirmative support of this theory we have from France the statement that the hypnotic influence has been forwarded by mail through the medium of a letter or postal card. We are informed that a young woman having an aching tooth which she was afraid to have pulled on account of the pain, received a communication by mail from a hypnotistic friend several hundred miles away telling her to go to a certain dentist and fall asleep while her tooth was being pulled. She did so, and felt no pain.

Now if I could bring myself to believe this to be true, I would answer the request for my opinion on the "thrill over the wire" by simply telegraphing "Never felt it, but thrill is all right." But I do not believe the tooth yarn, nor do I believe that mesmeric or hypnotic influence can be sent either by post, telegraph or other intermediary. I think the young woman must have deceived herself. Her sleep was probably imaginary, and furthermore,

the operation might not have been painful even though she had not received the letter. I strongly suspect that if the letter had informed her that the dentist would charge her fifteen dollars for pulling the tooth she would have experienced great pain and would not have slept for a week.

Now as to the "thrill over the wire," I have been thinking backward over the many years and wires covered by my own experience as a telegraph operator, looking for "thrills," as it were, but I am unable to join in the liberal corroboration of this operator's experience which his story is said to have brought out. If he had said he was thrilled by a first-class lightning sender, and was able to take the sending, *and put it down*, I would go a long way in his direction, for there is glory in being able to tell a great sender to "go" when he inquires after an hour's silence on your part "r–u–tr ?" But I was never thrilled, like the man who started this discussion, when working with an inferior operator. I have been strongly influenced under such circumstances, but not in the way he describes—rather more in the line of murder. I am sorry for it now, but couldn't help it then.

CURTIS' ELECTRIC RAILWAY CONDUIT.

We frequently hear the remark that while the progress made in electric railroading in this country is very creditable to American electrical engineering and to the enter-

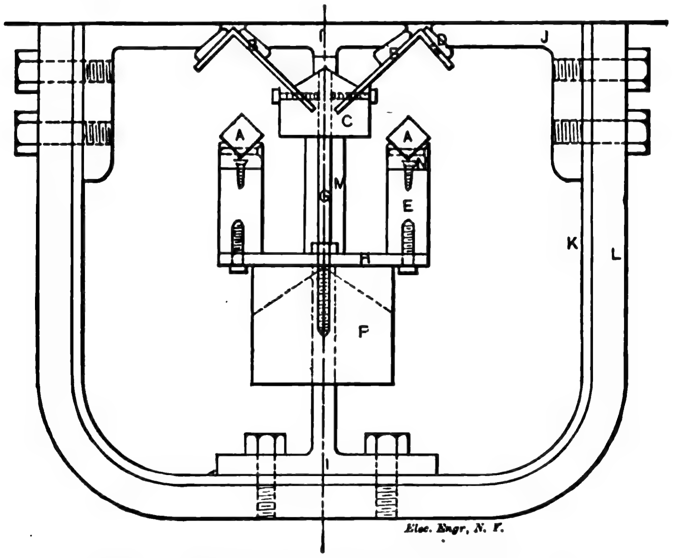

Fig. 1.—Curtis' Electric Railway Conduit.

prise of our railway companies, the time has come when the present methods of construction require some modifications to adapt them to the demands of an exacting public. This applies more particularly to the system of overhead wires now generally employed, but which is likely in the future to interfere seriously with the extension of electric railway work, at least in our largest cities. With this obvious fact in view not a few electrical engineers are wisely devoting their attention to the best methods of leading the current in conductors placed in conduits. The problem is by no means an easy one and involves many difficulties which must be overcome to insure success. Principal among these is the drainage of the conduit and its maintenance free from dirt and other street refuse, while at the same time permitting of making a good contact with the conductors within.

To secure this desideratum Mr. H. N. Curtis, of this city, has recently designed a form of conduit in which the slot through which contact is established from the conductor to the motor on the car is normally maintained closed, and only opened at the point at which the car happens to be at the time. The accompanying engravings show the manner in which this is carried out, Figs. 1 and 2 showing respectively a vertical and longitudinal section of the conduit.

The latter is built up of sheet iron K bolted to the heavy

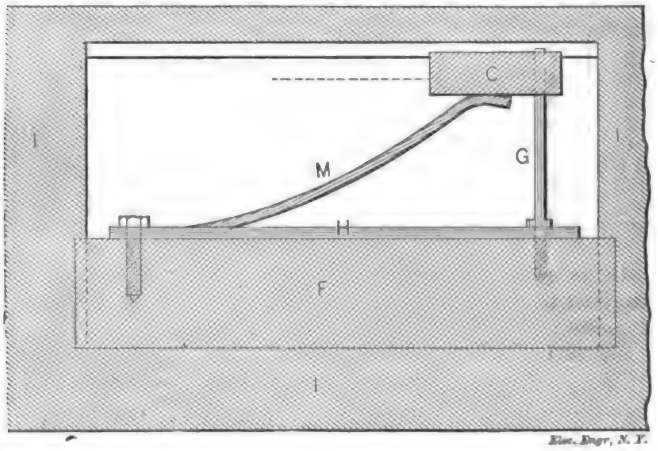

Fig. 2.—Curtis' Electric Railway Conduit.

collars L. In the centre of the conduit there is firmly bolted an I-beam I which reaches to the top and, together with the two angle bars J at the side, serves to form the two slots. The conductors AA, of rectangular form, are supported upon insulating pieces E, screwed to an iron plate.

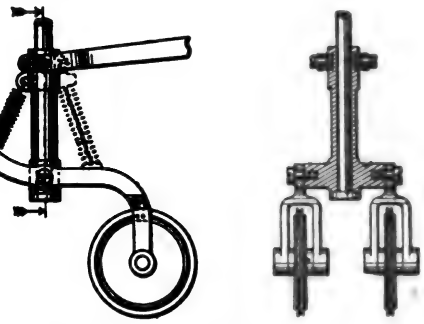

Fig. 3.—Trolley Wheels.

The slots, as will be seen, are closed by angle bars B upon which are fastened rubber strips that effectually seal the conduit and prevent the entrance of water and dirt. These angle bars are fastened in insulating connecting blocks C, which are pressed upward by the spring M, and maintained in a central position by the guide rod G. The bars B are made in lengths of three or four feet and joined together

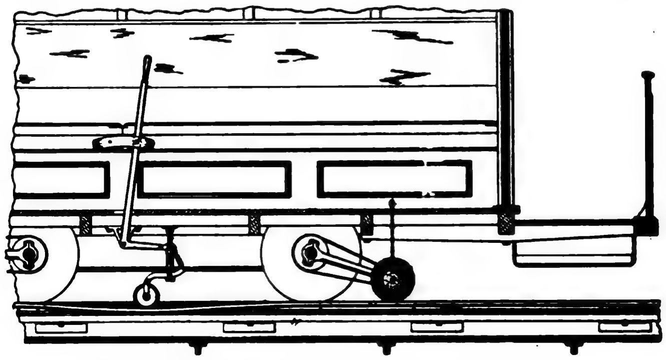

Fig. 4.—Curtis' Electric Railway Conduit.

flexibly so that they form a continuous length which can be depressed.

It will now be readily seen that as the car travels along, the trolley wheels shown in Fig. 3 depress the bars B and bring them in contact with the conductors in the slot, in the manner shown in Fig. 4, the current thus passing from

the conductor through the bars and trolley wheel to the motor on the car.

As soon as the pressure of the trolley wheel is removed, by the passage of the car, the flexible contact strip returns to its normal position by the pressure of the supporting springs by which it is upheld. A rotary brush attached to the car in advance of the trolley wheel clears the contact strip of all foreign material.

The insulating strips which protect the flexible metallic contact strip from the jaws of the conduit slot fit sufficiently close to practically exclude dirt, moisture, and all foreign material from entering the conduit. That which does fall into the conduit, can readily be removed through sewer connections by a brush or by flushing the conduit.

THE COMPARATIVE ECONOMY OF ELECTRIC, HYDRAULIC AND STEAM ELEVATORS.

The erection of high buildings makes the installation of elevators for the transportation of passengers a necessity. The nature of the service is one, however, characterized by such variability in load that the economy obtainable in other power applications had until recently been largely sacrificed to other considerations, when the advent of the electric motor placed in the hands of the engineer, a machine characterized eminently by its qualities of regulating the power consumption to the load.

In order to bring out clearly the relative economy of the electric elevator over the usual types of hydraulic and steam elevators, we give below a discussion of this important question by a well-known steam and mechanical engineer:

The questions which should have influence in making a decision as to elevator service, should be, efficiency, safety, economy of operation, durability and space to be occupied in the building by the operating machinery, and lastly the first cost of the plant.

In all of the elevator machinery as now constructed, the cost of operation so far as coal is concerned is altogether too great, and is in all cases, with the exception of the water-balance elevator, very nearly the same, whether the elevator is carrying its maximum or minimum load. The water-balance elevator is at its best when it has to carry its load from the bottom to the top of the building, without any intermediate stops, and consequently no change of its load during the trip; but even the water-balance elevator under these conditions, which are the very best it can be operated under, consumes twice the amount of power which should be necessary to do the work, as the following statement will show.

Let us consider the water-balance elevator, having a maximum capacity to lift 2,000 lbs. of load, the car and cage will weigh about 2,000 lbs., 1,500 lbs. of which will be counter-balanced. That leaves 2,500 lbs. to be lifted when the maximum load of passengers is in the car; but as the average load carried on passenger elevators is not more than one-quarter the maximum, which in this case would be 500 lbs., then we have for an average load carried during the day, 500 lbs. of passengers and 500 lbs. of counter-balance, and as carrying the counter-balance is so much dead loss, it follows that even the water-balance elevator in its very best condition of work, wastes just one-half of the power. In other words, when it lifts 500 lbs. of passengers, it at the same time has to lift an equal weight of uncounter-balanced car, for which it has no compensation. This is the condition of the water-balance elevator, which so far as the question of economy alone is concerned, is the very best of all the elevators now built.

The next elevator to be considered in economy of coal in its operation, is the direct connected steam machine. Now while it is possible to build a steam engine to run an elevator and use steam in proportion to the load which it has to raise, it is a fact that such an engine has never been built, and, practically, the steam engine driving an elevator uses just as much steam to lift the passengers direct, as it does on the water-balance machine to pump the water and lift the passengers through the agency of hydraulics. Theoretically, from the nature of the contrivances, this should be so, and in practice the results obtained, bear out this statement. But these two machines being considered, one as against the other, the steam machine is to be preferred —first, because it costs less; secondly, it takes less room in the building, and all things considered, it is less liable to accidents which endanger life.

Now, as to the ordinary types of hydraulic machines, whether they be direct lifts or the vertical type of machine, or whether they are of the horizontal type, one feature is common to them all. This feature is, that their consumption of water per trip, and consumption of power to furnish that water, is exactly the same for all loads; that is to say, they use just as much power to carry the elevator boy to the top of the building and bring him down again, as they do to carry the maximum capacity of the machine. The extravagant use of fuel in all this type of machines is something phenomenal, when the work which is done is considered.

If we take the steam from the boiler and follow it to the simple duplex pump, or to the compound duplex pump, we will find in elevator service, that for each actual horse power of water delivered into the tank, whether it be on the roof or the pressure tank in the basement, the enormous quantity of eight pounds of coal is used. Now, after we have got the water into the tank ready for use, we waste four-fifths of this power; one-fifth is thrown away in lifting the uncounter-balanced car, and three-fifths in having to use the maximum of water for all loads, while the average of all loads is but one-quarter of the maximum. These features are, as remarked before, common to all hydraulic elevators.

The steam machine is but a trifle better in economy, for the reasons stated previously, because the back pressure on the piston always rises to correspond with the decrease of pressure upon the steam side. The water-balance elevator uses water in proportion to the load lifted, whenever the loads are brought down at all times equal to those which are carried up, but as a large portion of the trips are made with small loads coming down, and many times with none but the operator on the car, it is necessary to make the counter-balance less than the car by about the average load lifted, so that the water-balance elevator, at its best, uses twice as much power as it should, to accomplish the work.

As to the question of cost of the water-balance elevator, the direct-steam, or the vertical or horizontal hydraulic, they come in order as follows: The cheapest is steam, the next is the water-balance, and the next hydraulic, either vertical or horizontal, which are practically the same.

The amount of *useful room* occupied in the building, is least with the steam; next comes the water-balance; third, the vertical hydraulic, and fourth, the horizontal hydraulic. In considering the room occupied, of course there is taken into account all of the space occupied by cylinders, tanks, pumps, etc.

To produce an elevator which should be reasonably cheap, efficient and safe, and at the same time use power in proportion to the load lifted, has been the dream and study of all principal elevator builders of the world. Such elevators are now built and operated by electricity. An elevator of this type is less in first cost of any, requires less room in the building than any other, and can be operated with less than one-half the amount of coal of any other. The best arrangement possible for an electric elevator is to place the machinery at the top of the elevator shaft above the travel of the car, for the following reasons: First, in that position the machinery occupies no otherwise useful space in the building, and in that situation the machine can be so counter-balanced that the amount of power required at any one time, whether the car is ascending or descending, is only sufficient to move half of the maximum carrying capac-

ity of the car. The same machinery however may be placed at the bottom of the elevator shaft, in the basement, occupying about the same room that an ordinary steam machine does. In either case it will use the power in proportion to the load carried.

In order to make this statement clear, as to the economy of the electric elevator when compared with the hydraulic, it is necessary to show where the power is lost in each case, and where the difference lies. First, the duplex steam pump, uses eight pounds per hour for each horse power; the engine which drives the dynamo to furnish electricity uses at most four pounds. Only one-fifth of the power developed in the steam pump is utilized in lifting passengers. In the electric, three-quarters of all the power which is developed by the driving engine is used for operating the elevator; besides, in all large buildings there are electric lights, and electricity is used for various purposes, and must have an electric generator in any event.

As to the question of safety, with all these various types of elevators (leaving out the water-balance), there is practically no difference. The safety appliances which are on one machine, may be applied to any or all.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—VII.

(*Copyright, The Electrical Engineer.*)

BY HERBERT LAWS WEBB.

CONDENSERS.

In comparing small capacities, such as those of over-head lines or short lengths of underground cable, it is a great convenience to be able to adjust the standard condenser to give about the same deflection as the wire or cable to be measured, and the accuracy of the test is also greater than if widely different deflections are obtained. The convenience, therefore, of employing an adjustable condenser, the sections of which can be connected either in parallel or in series, is obvious.

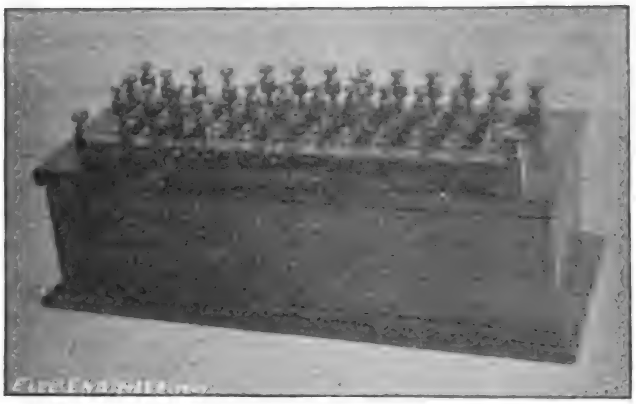

Fig. 24.—Condenser For Testing.

Fig. 24 illustrates a condenser having a total capacity of 4 microfarads and a range of capacities from .00985 microfarad up to the limit. This condenser has twelve sections; one of 2 microfarads, one of 1 microfarad, and ten of one-tenth each. The alternate plates of each section are connected to small brass blocks, insulated from the long strips running the full length of the condenser; the plugs are provided with small binding screws, and for connecting the sections in series they are inserted in the holes in the blocks and connected diagonally with short pieces of wire, the two end blocks of the series being plugged to the long strips so as to make connection with the discharge key and earth.

In Fig. 25 an improved form of the multiple series adjustable condenser is shown. The blocks are arranged so as to overlap each other, and the different sections can be joined in series by means of the plugs alone without the use of connecting wires. The plugs are fitted with binding screws so that the different sections can be used as separate condensers if desired, each section being rendered independent of the others by connecting wires to the plugs and inserting them in the blocks. This instrument is the *ne plus ultra* of adjustable standard condensers; the style illustrated is divided into five sections of one-tenth each, and has a range of capacities from .02 microfarad to .5 microfarad.

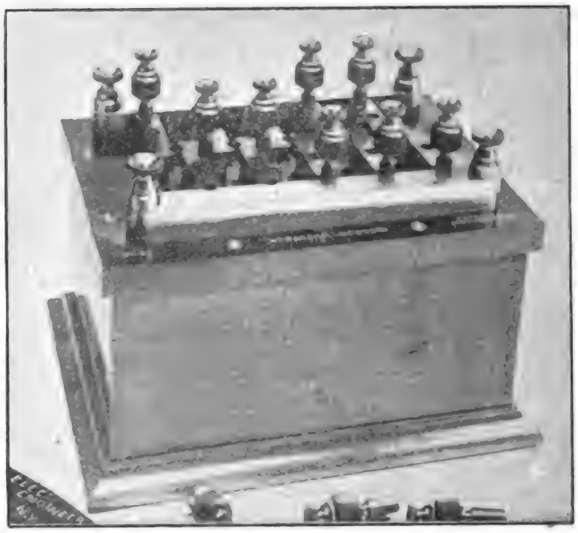

Fig. 25.—Improved Multiple Series Adjustable Condenser.

When not in use, standard condensers should always be short-circuited by inserting the plugs between the brass blocks to which the plates are connected; in this manner any residual charge is neutralized.

TESTING BATTERIES.

For testing purposes a battery of at least 100 cells is necessary, and in cable factories it is customary to use 200, or even as many as 500.

A set of accumulators form an ideal battery for testing, but a large number of secondary cells is seldom available. The next best is some form of Daniell, either the origina Daniell or the Minotto, but not the ordinary gravity batteries, as the solutions in these cells diffuse quickly unless the battery is doing constant work. In many cases Leclanché cells are used for testing batteries and answer very well, as they require very little attention.

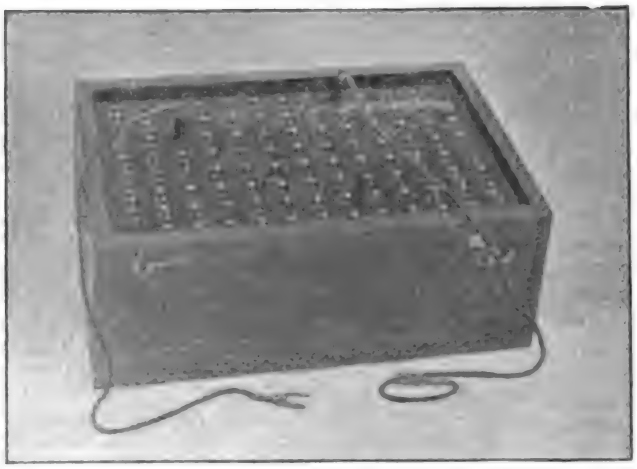

Fig. 26.—Chloride of Silver Battery—100 Cells.

The battery most frequently used for testing work in this country is the chloride of silver cell, made up in sets of 50 or 100. This battery has great advantages over all others in point of compactness and portability, and the ease with which any number of cells may be connected. The chloride of silver cells require very careful handling to keep them in good order, as, if the battery is worked on a low resistance, or short-circuited, several damaged cells will probably be the result. As portable testing sets do not always receive the most careful handling, these batteries frequently need the attention of the manufacturers to keep them up to the mark. The cells have a pretty high internal resistance to start with, and this increases with time, mounting up sometimes to an alarming figure.

The small commutator usually provided with the portable testing batteries should never be used. It is a most unsatisfactory and vexatious instrument, always working loose and making bad contact; or, if screwed up tight, metal dust is ground off the points and distributed over the plate so as to partially short-circuit the battery. It is somewhat surprising that the manufacturers of the batteries should still cling to this very inefficient style of reverser.

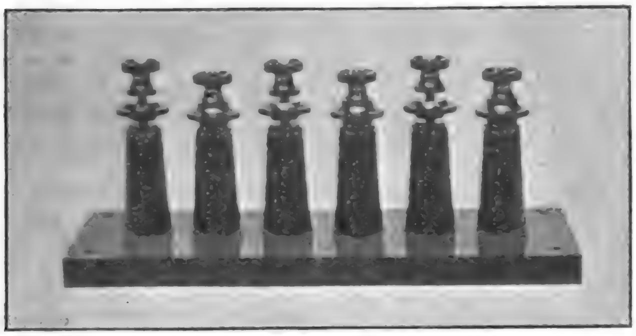

FIG. 27.—INSULATED DOUBLE BINDING POSTS.

In Fig. 26 is illustrated a 100 cell chloride of silver battery. The fixed commutator is discarded and the connecting cords are provided with forked tips by means of which they can be connected to a battery reversing key of proper design (such as that shown in Fig. 14). The cover of the case is made entirely removable instead of being hinged, this arrangement being more convenient for work in a permanently fitted up testing room.

The testing battery should be placed in a well protected situation so that it may be kept free from dust and dirt, and above all the entire battery should be thoroughly well insulated, as a badly insulated battery will disorganize the work and render the tests valueless. If Daniell or Leclanché cells are used they should be placed on wooden stands raised from the floor or shelving by means of hard rubber feet about four inches long; the cells should be well separated from each other and the glass jars should be kept dry and clean; they should be frequently inspected and any incipient signs of "creeping" must be attended to at once. It is of great importance in testing that the battery shall be perfectly constant; any slight defect in the battery will affect its constancy and neutralize the value of the tests. Therefore, too great care cannot be taken in avoiding the appearance of any such trouble, or in remedying it after the slightest indication of its existence.

In a testing battery the cells are of course always connected all in series, as for insulation tests the full E. M. F. is generally required. In measuring conductor resistance and electrostatic capacity it is only necessary to use from five to ten cells. With the chloride of silver battery it is a very easy matter to connect any desired number of cells to the battery reverser, as one pole of each cell terminates in a small nipple on which the plugs of the connecting cords fit tightly, and in order to vary the number of cells the only operation necessary is to alter the position of one of the plugs. With a battery composed of 100 Leclanché cells permanently connected in series, the question of changing the battery power quickly is not so simple, involving the connection of wires, which is rendered additionally troublesome when the battery, as is generally the case, is placed in a more or less inaccessible position.

The best plan of getting round this difficulty is to provide a number of insulated binding posts on the testing table to which wires from the battery may be permanently connected; it is then an easy matter to join up the battery key with the number of cells required for any particular test.

Let us assume that we have a battery of 100 cells. To the testing table, or to the wall at the side, or in any position that may be most convenient and accessible, is screwed a set of double binding posts mounted on hard rubber pillars and base. To the binding post number one a wire is run from the zinc pole of the battery and the carbon pole is connected to post number six; to the intermediate posts wires should be run from the carbon poles of the first, fifth, tenth and twentieth cells. One terminal of the battery reversing key being connected to the zinc binding post, it is an easy matter to connect the other terminal of the key so as to obtain battery power of one, five, ten, twenty, or the full number of cells, by simply changing one wire. These combinations of cells are all that will be required for general testing, and the connections from the battery to the pillar binding posts once made, the battery need never be touched except for inspection or removal of defective cells.

A set of insulated double binding posts suitable for making the battery connections described above is shown in Fig. 27.

The testing room is generally some distance from the terminals of the cables to be tested, or, in a factory, from the tanks in which the wires and cables are submerged. This separation, however inconvenient, is necessary in order to secure quietness and freedom from magnetic and mechanical disturbances likely to affect the steadiness of the galvanometer.

In order to make connection with the cables to be tested, a number of permanent leads, which should be of the best possible description, heavily insulated and well protected from mechanical injury, are run from the testing room to the terminal room or cable-tanks. It is best to terminate these leads at the testing table on a set of the insulated double binding posts described above; the ends of the leads are then protected from damage and the insulation afforded is excellent; the pillars can be numbered to avoid confusion and any lead can be connected with the testing instruments by simply joining a short piece of wire from the key to the binding post on which the lead required terminates.

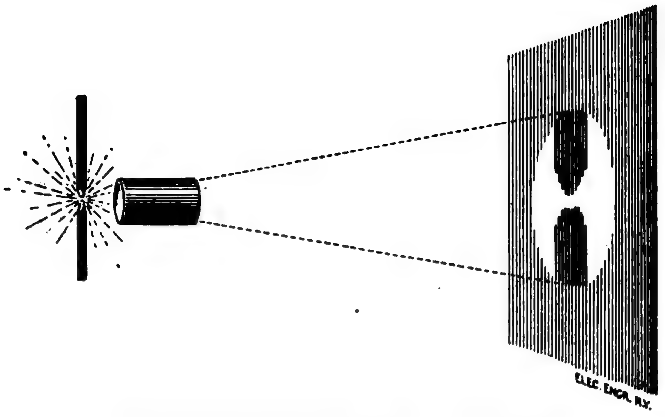
TELEPHONE WORK IN JAPAN.

Many of our readers will remember the visit to this country from Japan of Mr. S. Oi, a Japanese electrical engineer. In a recent letter to Mr. G. M. Phelps, he says: "Since my return from America, I have been entrusted with the whole affairs relating to the establishment of telephone exchanges in Tokio and Yokohama. We don't have many subscribers at present, but as far as I can see, the exchange is getting more and more popular and we have many applications in succession day after day. We opened the exchange here in Tokio, about a month ago. The annual subscription is about $32 in Tokio and $28 in Yokohama anywhere within the limits of the towns. As there is no need of using multiple switchboards at present, we use an ordinary type of switchboard made here in Tokio. We use conductors of No. 18 hard copper. That I have been enabled to finish the exchanges successfully is principally due to the kind assistance I had received in the States in making investigations in the various exchanges." Mr. Oi adds that Mr. Sawai, an electrical engineer who is also well known in this country, has been ill and is at present ruralizing 400 miles from Tokio for the recovery of his health. Mr. Oi is now attached to the Department of Communications of the Telegraph Bureau.

TESTING ARC LAMPS.

BY FRED. H. COLVIN.

There is in use at the main Brush Electric Light Station, Philadelphia, an ingenious and praiseworthy arrangement for testing the arc lamps before they are sent out, or on repair work. It is praiseworthy because it saves the



Simple Method of Testing Arc Lamps.

eyes of the workman and ingenious because of its novelty.

The testing rack is of the usual form, but in front of each lamp is placed a lens which is provided with a rack and pinion focussing arrangement, and fitted in a horizontal sliding way or frame so as to be readily adapted to each carbon.

The lamps to be tested are switched on as usual, but the operator, instead of watching the carbon points themselves, adjusts the lens to focus on the white wall several feet away, and there watches the enlarged and inverted image of the carbons in all their processes of burning, and sees much more accurately than if he watched the carbons themselves. This does not injure the sight to any perceptible degree, and is not only humanitarian, but gives a clearer idea of the action of the carbons.

The accompanying figure will illustrate the plan quite clearly.

SABOLD'S GROUND CIRCUIT FOR ELECTRIC RAILWAYS.

The experience thus far gained in electric railroading has shown that too much attention cannot be given to the integrity of the ground or return circuit, and our columns have already contained numerous descriptions of devices and arrangements designed to effect this purpose.

The cheapest form of construction, which is, of course,

Sabold's Earth Return for Electric Railways.

the most unreliable in operation, is that in which the track-rail alone is depended upon as a return conductor. This system is found only on suburban roads where the traffic is so light as not to warrant the addition of supplemental wires, which are laid on more important roads at considerable expense.

But even in the latter case, the result of practice has shown that in numerous cases the ground wires have been rapidly attacked and reduced in effective section by corrosion, due largely in all probability, to electrolytic action.

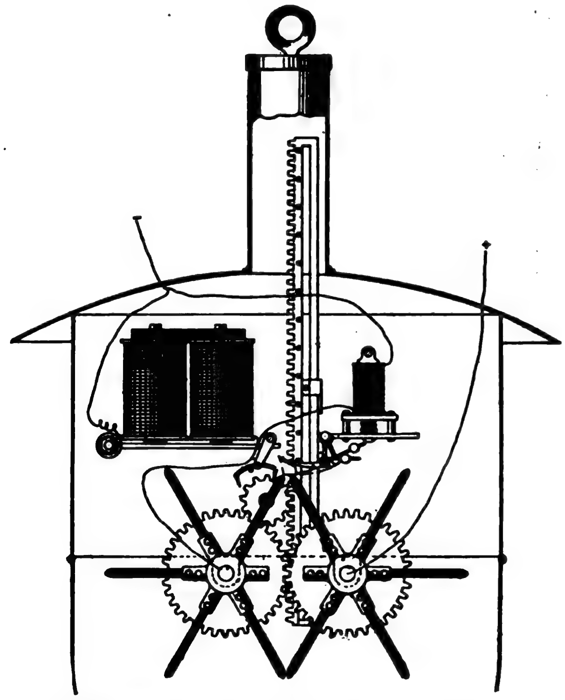
To this must be added the fact that in numerous cases the single trolley system of operating electric railways has given rise to grave troubles in telephone circuits located not only in proximity to the car line circuits, but even in those situated at a considerable distance. Investigation soon showed that this was due not so much to induction between wire and wire, as to an actual leakage by conduction; the railway current, notwithstanding the return wires, escaping to ground and seeking other convenient paths, such as the telephone wires, in returning to the dynamo at the generating station.

To afford an effective return circuit for the current and at the same time to avoid interference with telephone circuits, Mr. F. W. Sabold, of Albany, N. Y., has designed and recently patented a system which is now in successful operation on the lines of the Albany Railway Co., as well as in Troy, N. Y., and the work of equipping the Watervliet railway, extending from Troy to Albany, is now being carried out. In all these places the interference with the telephone service was so serious as to make the telephone practically useless, but the introduction of Mr. Sabold's system has remedied the trouble.

The method employed is exceedingly simple and consists, in the first place, in relying on the earth entirely as the return circuit; and in the second place, in connecting each rail directly to earth. The plan adopted by Mr. Sabold is shown in the accompanying engraving. As will be seen, each rail is connected by a conductor with an iron rod driven into the ground to a depth at which moisture is constantly present. As the car moves along the track, the current finds at every rail a good ground, and thus has no tendency to take up other indirect paths to reach the generating dynamo. It will be noted also that with this construction the bonding of the rails is of minor importance, and, as no return ground wire is required, the expense of the equipment is greatly reduced.

HENDERSON'S MULTIPLE CARBON ARC LAMP.

The cost of trimming arc lamps was very early recognized to involve a not inconsiderable part of the total operating expense in arc lighting, and to this fact the creation



Henderson's Multiple Carbon Arc Lamp.

of the double carbon lamp is due. But even the saving effected by the latter has not deterred inventors from seeking to still further increase the intervals during which the arc lamp may remain without attendance and has given rise to various forms of carbons and devices for prolonging

their life. Still another method which has lately been brought out consists in providing a number of sets of carbons, each of which is successively brought into action, as its predecessor is consumed.

A lamp based upon this principle and recently patented by Mr. W. B. Henderson, of Crafton, Pa., is shown in the accompanying engraving. The inventor, it will be noted, employs six pairs of carbons, mounted on two hubs which are controlled by the lamp mechanism. Each pair of carbons starts into operation at an angular position and as they burn away the hubs are revolved so as to bring the points towards each other; so that when fully consumed the carbons are exactly in a horizontal position. When this point is reached, the mechanism automatically brings the succeeding pair of carbons into circuit and this operation is continued until all the carbons are consumed.

TIGHT BELTS.

BY ROBERT GRIMSHAW.

This is not to be an article advocating tight belts; rather one upon the tightness of belts, and complaining that belts are more often too tight for their good and for that of the shafts which they connect, than too loose. I suppose that about as good a heading might have been "Tight Lacing," the only objection to it being that there are so many other methods of fastening now-a-days than lacing, and that many belts are made endless.

It is usually set down in text books, and in ninety-nine cases in a hundred in the "experience boxes" of men who call themselves practical, that the tighter a belt is (other things being equal) the more it will drive. I had the honor of being the first, so far as I know, to point out that this was true only to a certain extent; that there was a limit, with each kind of belt and each set of conditions, beyond which further tightening not only gave no further increase of driving, but actually lessened the capacity of the belt —to say nothing of the injurious effect upon belt, fastenings, and shaft bearings.

What is that "slipping point," beyond which no further tightening will give more driving power? And why does it exist?

We had better answer the second question first. We know that the tendency of the pull on a belt is to bed it down to the face of the pulley, thus bringing more and more of the surface in contact with the pulley face, according as the tension is made greater and greater. A belt that is soft and flexible will, of course, bed down better than one which is hard and stiff; a surface which is not deformed by rivets will bed down better than one which is not smooth and flat. The effect of bedding a soft surface down to the pulley face is to change its character. A surface which is comparatively porous, or rough, becomes smooth by the pressure, and with some kinds of belts takes on a sort of a glaze—only temporary in some cases, permanent in others. A glazed surface will not drive so well as one which is unglazed; and more harm may be done by glazing the surface, either temporarily or permanently, than can be balanced by the advantage of having the belt touch the pulley all over its surface. In other words, if before excessive tension was resorted to, the belt touched the pulley with three-fourths of its surface, and if after excessive tension was put on, it touched over the whole surface, we would expect one-third increase in the driving power, as a maximum. But if the character of the three-fourths which touched the pulley before straining, is so changed that each square inch of it is only as good as one-half square inch was before, we have the value of the three-fourths lessened to three-eighths, and this plus the new one-fourth which we will assume is as good as any equal portion of the three-fourths, makes only five-eighths, which is not as much as three-fourths.

This is the theory of the thing, and it is simply borne out by tests made in a belt-testing machine and by experience with belts running in saw-mills, electric light plants and other establishments. It is more so with leather belts than with raw hide; more so with leather and raw hide than with cotton, and more so with cotton than with rubber. At least, this is the general run of things. There are exceptional cases where the order in which these belts are affected by excessive strain, is varied; but in all cases the fact remains, that there is a point beyond which further straining not only does not give further driving power, but actually lessens it—to say nothing of the injury to belt, to fastenings and to bearings.

The moral of all this is to run your belts loosely; then you will be sure that you are not hurting them, while at the same time lessening their driving power. So long as a belt will start its driven pulley suddenly, it is tight enough for the work. It may be tight enough to run the job right along and yet not be able to start a machine from a state of absolute rest; particularly if there be heavy rotating parts which absorb power during quiet running, to give it out when needed to overcome a sudden excess of load.

Of course I do not mean that a belt should be run so loose that it would flap and weave; but so long as it runs quietly and without slinging from side to side, it should be allowed to be as loose as it can be slacked up to, and yet drive the load. And if there be a flapping fold running from the driving to the driven side, it is much better to take it up by an idler pulley near the smaller of the two pulleys connected by the belt, than to take up the slack at the fastening.

Idler pulleys are great things if people will only distinguish between them and tighteners. An idler should in no way increase the strain at the fastenings; should in no way increase the pull on the bearings; that is the test. The minute that it does this it is not an idler, but a worker, and a mischievous worker at that. The proper way to apply an idler is so that it will increase the wrap on the pulley on which the belt drives the most poorly. (This is not necessarily the smaller of the two pulleys, for sometimes a small wood pulley will have more grip upon a belt than a large one of iron; sometimes a small iron pulley may be lagged with leather or paper so as to drive better than the larger one over which the belt runs.)

Of all the ways by which a belt may be made to drive more, giving it greater tension may be regarded as the poorest all around. Give it more arc of contact; give it better pulley surface, run it faster—do almost anything except increase its tension. Of course, increase of width or of thickness gives increase of driving power under similar circumstances, but that means another belt, and should not be resorted to so long as the simple means of giving more arc of contact, better surface to grip on, and greater speed, remain untried.

MR. MACKAY'S IDEA OF CHRISTMAS.

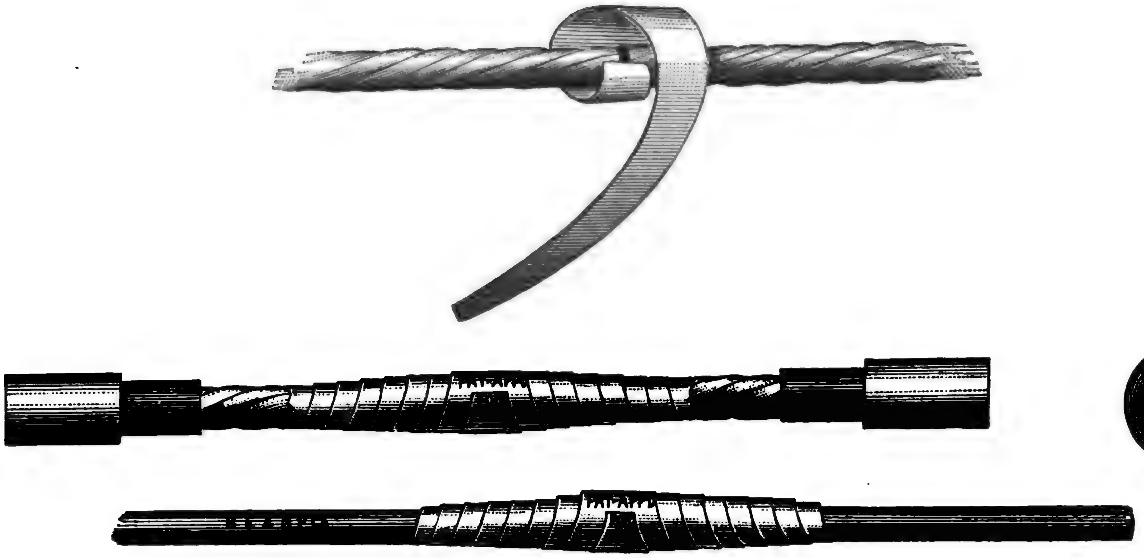
Mr. John W. Mackay, following a generous custom that he set some years ago, has again authorized General Manager Ward to give every employee of the Commercial Cable Co. in this country and in Europe, half a month's salary as a Christmas present.

ELECTRIC LIGHTING IN NEW YORK CITY.

Within a short period electricity will again take the place of gas for street lighting purposes in the districts where the electrical subways are laid. The electric light companies have held out for several months for forty-three cents a night for each arc light, but in accordance with an informal agreement with the city authorities they have decided to accept forty cents. Before Commissioner Gilroy's onslaught on the poles and wires began there were 1,275 arc lamps in use, for each of which the city was paying thirty-five cents. At present there are about 800 lights in use, for which the old price is still paid. The city has been willing to pay this figure all along, but forty-three cents has been considered entirely too high. The figure which has been agreed upon is the result of a compromise, and 250 old lamps will be lit up again in addition as the result of it.

BERGMANN'S NEW CONNECTOR FOR ELECTRICAL CONDUCTORS.

NEXT to the quality of the conductor itself the most important part of an electric circuit is the joint by which its various lengths are connected to form the complete lines. In all classes of electric work the joint has been found to exercise a not inconsiderable influence on the working efficiency, and as a result we find that constant efforts are being made to improve not only the quality but the ease of accomplishing the union of two ends of a conductor. A good joint should have two important attributes, namely, a conductivity and a tensile strength at least equal to that of the rest of the circuit.



FIGS. 1, 2, 3 AND 4.—BERGMANN'S CONNECTOR FOR ELECTRIC WIRES.

To combine both of these merits with facility in making the joint, the Bergmann Electric & Gas Fixture Co., of this city, have just brought out a unique connector which is specially adapted to the jointing of heavy wires, such as those employed in electric lighting, railway and welding conductors.

The connector employed for this purpose consists simply of a strip of No. 34 sheet copper tinned on both sides, made in various widths and lengths, tapering at one end to about 1½ to 2 inches in width and also slightly tapering towards the other end. The manner of its application is illustrated in Fig. 1, which shows a stranded cable about to be wrapped, Fig. 2 showing the completed joint and Fig. 3 a section of the same. Fig. 4 shows the connector as applied to a solid wire.

In order to make the joint conveniently and rapidly, use is made of a simple clamp stand, which is illustrated in Fig. 5.

The two ends of the cable or conductors to be joined are tightly clamped in the jaws on the stand and the ends brought to within about $\frac{1}{16}$ inch of each other; the handle in the middle of the stand then being given a turn the two ends are brought up close to each other. Then by means of a soldering iron or torch, one end of the copper strip is soldered to the cable and the strip wrapped tightly around the cable ends, acid being applied to each layer. The end of the strap is then bound together by iron wires, about $\frac{3}{4}$ of an inch apart. The whole connector and cable ends are then heated with a good flame and solder applied, after which the iron wires are removed, leaving a perfect joint.

It will be readily seen that the conductivity of a joint made in this manner is fully as great as, if not greater than, that of the conductor itself, and in order to demonstrate its mechanical strength we give below the results of tests made at Columbia College on samples of a No. 2 silicon bronze wire having an area of .043 sq. in :

	Breaking Stress.	Area of Complete Joint before Fracture.	Diam. of Joint.
No. 1	2,140 lbs	.169 sq. in.	.465 in.
No. 2	2,080 "	.165 " "	.459 "
No. 3	2,800 "	.155 " "	.445 "

The normal breaking stress of the wire was 3,490 lbs.

It will be noticed that the connector increases the diamete, but comparatively little at the joint, which is of special importance in insulated conductors. On the other hand the connector is admirably adapted to overhead trolley lines, the joint being perfectly smooth and round and presenting no obstacle whatever to the passage of the trolley wheel.

Another practical convenience, we need only add, is that the connector can be applied to any size or style of cable or bar without requiring a special size of connector for each variation in the diameter of the conductor.

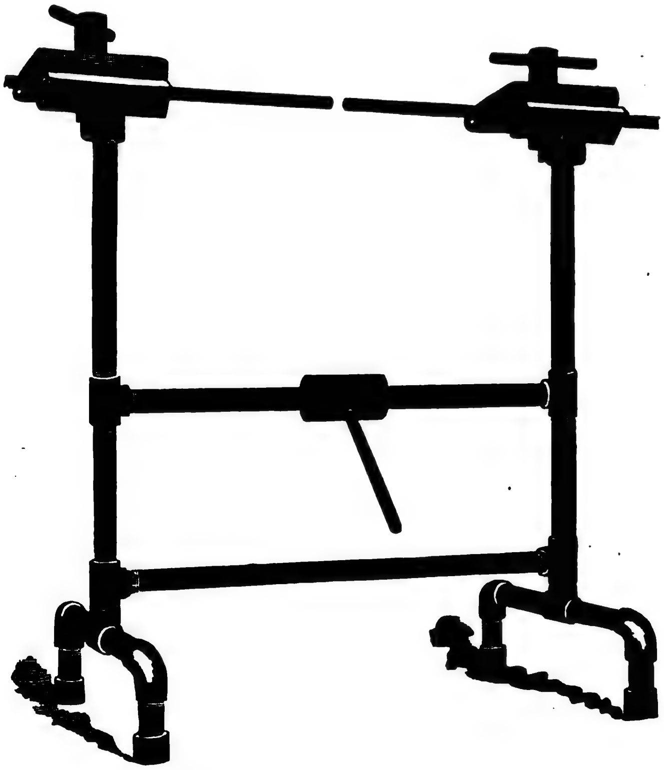


FIG. 5.—THE CLAMPING STAND.

THE
ELECTRICAL ENGINEER.
[INCORPORATED.]
PUBLISHED EVERY WEDNESDAY AT
150 Broadway, New York City.
Telephone: 3860 Cortlandt. Cable Address: LENGINEER.
GEO. M. PHELPS, President. F. R. COLVIN, Treas and Business Manager.
Edited by
T. COMMERFORD MARTIN AND JOSEPH WETZLER.
New England Editor and Manager, A. C. SHAW, Room 70—680 Atlantic Avenue, Boston, Mass.
Western Manager, W. F. COLLINS, Temple Court, 225 Dearborn Street, Chicago, Ill.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. X. NEW YORK, DECEMBER 31, 1890. No. 139

Science teaches us to deduce principles carefully, to hold them firmly, or to suspend judgment, to discover and obey law, and to be bold in applying to the greatest what we know of the smallest. —Faraday.

PREPARING FOR THE WORLD'S FAIR.

PRESIDENT HARRISON has at last issued his proclamation and invitation regarding the Columbus Fair, and the preliminaries appear to be settled, although we question whether anybody outside of Chicago can give a clear statement of the situation, so confused has it become through prolonged jangling and discussion. It cannot be said, moreover, that Mr. Harrison's attitude is a particularly happy or pleasing one, holding out to the nations as he does an expression of brotherly good will in one hand and the McKinley tariff in the other. In view of the fact that the Exposition is to be held so far from either seaboard, it was desirable that, in order to make it international, as few difficulties should be placed in the way of foreign exhibitors as possible, but the latest piece of legislation looks just as though its authors owed Chicago a grudge and were paying it off by trying to keep European exhibitors away.

Still Chicago is a city of great resources, abundant wealth, high courage, and indomitable perseverance, and we expect to see her make a grand success of the Exposition, even though it be narrowed down to a National Fair. If foreigners do not come to show us what they can do, they will at least come to see what we can do and to make acquaintance with the infinite opportunities presented by this country for the investment of capital and the settlement of population. If Europe were to have a Fair limited to its own productions, it would certainly suffice as evidence of the progress of mankind in the arts and sciences; and to-day, the same thing may fairly be said of America, young as it is and with large portions of its soil still unpeopled and in the virgin state. If each American industry and each American commonwealth will but do its duty, the Fair of 1893 will be all that the most patriotic and most enthusiastic of us could wish.

An inquiry has just been addressed to electrical firms and companies, by President Davis, of the Fair, asking them to say how much space they are likely to want. The response to this will not be binding but will indicate approximately, it is thought, the area required for the electrical exhibits. We trust that the answers will be made as fully and as promptly as possible, but we are afraid that there will be some slackness, not for want of interest, but because the necessity for reply does not seem immediate and because the appeal is not direct and personal. It would have been better if an authorized commissioner had received orders to call upon the various electrical concerns in each city and had then made a report of the result. It would also, perhaps, have been better if people knew the name of the official who is to have the charge and direction of the electrical exhibits. We say this, not at all to be critical, but because we are extremely anxious that the electrical section should be one of the largest and most striking, particularly in the matters of light and power. The Exposition should be wholly lighted by electricity, it should be wholly driven by electric power, and this means the early making of comprehensive plans by competent men.

ELECTRIC RAILWAY IMPROVEMENTS.

SIMPLE as the electric railway is in principle, the details of the methods now employed and approved require the most exacting attention in order to insure success, and that our inventors are keeping pace with the demand for improvements in this branch will become evident upon a perusal of our patent record each week. While formerly electric lighting and methods of distribution claimed the largest share of the patents issued we now find the patents on electric railways exceeding by far in number those in any other branch of applied electricity. Among the details of this work, the railway conduit claims a good share of attention, and deservedly so. There is to-day no more important problem to be worked out, than the providing of a suitable method of conducting the current from generator to car without the use of overhead wires. Thus far no systematic and determined attempt to carry out, and operate, despite initial discouragement, such a method of construction on a working line has been made in this country; but those who have been foremost in placing the electric railway where we find it to-day can assuredly be counted upon to meet every further demand as it arises, and though its solution be tardy, we are none the less sanguine that this conduit problem will be satisfactorily solved and at a very early date. The conditions to be fulfilled by a conduit system are exacting in the extreme and are aggravated to a great extent by the character of the streets in new and rapidly growing cities. As one solution of the problem, the system proposed by Mr. H. N. Curtis and described on another page will, we are sure, prove of interest, as embodying features which not only overcome most of the difficulties met with, but which allow of simple

methods of construction. It is evident that if the conduit can be maintained practically clear of extraneous matter, the removal of the latter becomes a question of secondary importance, and it is upon these lines that the conduit problem seems likely to be studied out to a successful demonstration on some large road. In this issue mention is made of the fact that a million dollar cable plant at Grand Rapids, Mich., is to be abandoned as such, and the trackway converted into an overhead electric system. Now it seems to us that the cable conduit thus vacated presents an opportunity to try some such promising system as the Wheless, lately described in our columns, the Harding, or the Curtis, now brought to notice. It seems to us also that the local street railway people would themselves have special interest in such a utilization of their old cable conduit, and in seeing whether, after all, they could not get along profitably without the overhead wires.

THE SIEMENS "H" ARMATURE.

The development of the original type of the Siemens "H" armature into that of the modern type with many commutator segments has relegated the consideration of the former to the background, but there are still some applications of the old type of armature, as, for instance, the telephone magneto call of which in the aggregate hundreds of thousands are in daily use and the number of which is constantly increasing. The results of some tests made upon a machine having this type of armature to determine the influence of the point of commutation, as detailed by Mr. J. Martin, in this issue, show that the efficiency and output can be considerably increased by proper attention to this matter. A little reflection on the subject must make it apparent that the distortion of the field produced by a two-pole armature shifts the point of commutation considerably from its theoretical position. Of course, this point is largely dependent upon the relative strengths of the field and armature and must vary in each case, but it is well to have attention drawn to a phenomenon involved in the daily operation of many instruments.

MODERN ELECTRICAL SUPERSTITIONS.

In his usual shrewd and humorous way, Mr. P. B. Delany discusses this week the stories that have lately been going the rounds of the newspapers about "the thrill over the wire" that one operator is supposed to be able to give another who happens to be sensitive to his mediumistic influence. The best way to treat such beliefs is to subject them to this kind of mild ridicule. It is only strange that they survive and "bob up serenely" time after time, first in one shape then in another. In the present instance, as proof of the statements made, the Charcot hypnotic experiments with magnets have been cited. The fact has been overlooked that Dr. Charcot repeated his experiments with dummy magnets of wood, and, as might have been expected, got exactly the same results. The fact has also been overlooked that Sir William Thomson demonstrated that even when the human body was subjected to a most intense magnetic field, no effect was obtainable, the person under treatment not knowing when the magnet, between whose ends his head was placed, was energized or when it was not. But the credulous victims of this kind of yarn do not care much for fact, it is fiction they are after; and they are very much of the same calibre as the other people who put arc carbon tips in their pockets as a cure for ague or ride in the electric cars to get rid of their rheumatism.

ELECTRIC CARS AND THE SNOWSTORMS.

The late unusually heavy snow storms have been very trying to the street car lines, but on the whole the electric cars have come through the ordeal very well, especially where the management of the road had been wise enough to include snow plows and sweepers in the equipment. Of course, in some places, the cars had to stop running, the deep snow obliterating the tracks for a while, but as other means of travel underwent stoppage also, including steam locomotion, the fact is not at all to their disadvantage. Besides, the point has been emphasized in more than one city, that while the horses were "eating their heads off" during the blockade, the electric plant, if shut down, was on a very economical basis and if in part operation was generating power in exact proportion to the demand for it. Another point brought out by the visitation has been that the single trolley roads have stood up much better than the double. It is reported that in Cincinnati the short circuiting on the double trolley road played havoc with the motors. It really looks as though the single trolley advocates had now carried the day most decisively.

ELECTRICITY FROM WIND POWER.

From the very moment that the storage battery became a practical, commercial apparatus its application to the storage of energy derived from the power of the wind was broached, but up to the present time very few attempts have been made to carry out the suggestion in practice. Our readers will therefore have been interested in the description given last week of the plant operated by Mr. C. F. Brush, for several years at Cleveland, O. When we consider the widespread application of wind power to the operation of pumps for elevating water it seems indeed strange that no determined effort has been made to apply the same power to the storage of electrical energy. In the latitude in which we live steady winds may be counted on for the largest part of the year, so that the only remaining objection would be the cost of a windmill storage plant. We can readily conceive that a single pioneer plant, such as that of Mr. Brush, might involve considerably more expense than a second or third of the same nature, and, again, that the average plant would not require to be nearly as large. It therefore seems pertinent to suggest that this field so entirely unoccupied at the present time be seriously considered, as we are certain that a profitable if not a large business can be developed in this direction.

Electricity is already utilizing thousands of horse power from water courses, and is preparing for even more extensive work at Niagara, and there seems no good reason why it should not utilize the wind. We hear of plans now and then for getting something electrically out of the sunshine and the tides, but while that may be a remote result, it should be easy enough to transform the power of rising winds and falling waters.

THE IMPROVED GRAMOPHONE.[1]

BY EMILE BERLINER.

It might seem strange to you at first that I should commence discussing the gramophone by talking about induction; but I would like to refer to a small portion of a paper which I read before the Franklin Institute in 1888 on the gramophone, when it was first shown, in which occurs the following:

"In my telephonic studies I had become familiar with all the causes influencing the transmission and reproduction of the voice, and what had at all times struck me as forcibly as anything in telephonic phenomena was the fact that the self-induction of long iron wires or of polarized electro-magnets acted so detrimentally upon the articulation. Electric resistance alone would simply have weakened the sound, but self-induction meant retardation and thus distortion of the transmitted waves which varied in length and amplitude."

And further on:

"In considering such and other facts it became evident to me, that if such delicate energy as the voice, subdivided into, maybe,

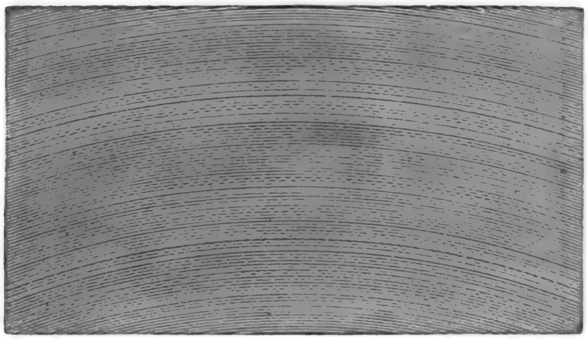

Fig. 1.—Gramophone Record.

several hundred waves should indent or engrave itself into a solid body, it needed but very slight mechanical resistance to modify considerably the character of the sound vibrations, for what self-induction is to the telephone circuit, the variable resistance which impressible material offers to indentation or engraving at various depths is to the phonograph record sheet. Neither is proportional in direct ratio to the expended energy, and must give cause, aside from a reduction in size of the sound characters, also to a distortion of the same."

And that brings me right to the subject of this evening, and I start by further explaining here, that those remarks had reference to the fact that in the phonograph it was impossible to make a loud reproduction which at the same time would be natural in tone. So long as you confine yourself to the small telephone voice the sound is natural and very satisfactory, but so soon as you attempt to indent at greater depth the waves are distorted and the sound becomes unnatural. In the gramophone, as you will further on see, and I suppose you are perfectly familiar with the principle, there is no indenting and no engraving, but there is a constant resistance, that of the light pressure of an elastic blade on a flat surface, or on a cylinder, if you please, but whatever resistance there may be, it is constant. And that is the principal difference, speaking scientifically, between the phonograph and the gramophone, that in one you have a variable resistance, in the other a constant resistance.

In May, 1888, before a meeting of the Franklin Institute, in Philadelphia, I showed publicly for the first time, how sound-records could be etched in metal, and how the original sound could again be made audible from such etchings. What I there demonstrated was of necessity crude in its effects, because embodied in the invention were a number of entirely new processes, new principles of construction and an art which dealt with motions infinitesimally small, the effects of which cannot altogether be either seen or measured; all of which was brought to bear on the single problem of fixing forever and with as much resemblance to nature as possible, both in loudness and quality, the sounds of instruments, of noises of all kinds, and of that delicate and subtle form of energy, called the human voice.

At the same meeting, I read a lengthy paper dealing with the history of the twin arts, that of transmitting sound electrically, and that of recording and reproducing the same mechanically. That the development of both arts occurred as I then showed—in parallel steps—is not the only excuse for bringing talking-machines before electrical societies.

In the gramophone, at least, there occur materials and processes, which, partly or wholly electrical, comprise terms familiar to every electrical engineer. Zinc, acid, bichromate of potash, diaphragms, dampers, electrotyping, all these play their part in the technique of the gramophone, not to speak of the possibility of applying electric motors to drive the machines, and of using the electric current for rapid etching.

The science of electricity almost began with immersing zinc in acid, but crude force alone is thereby set free, while in the gramophone, the action of the acid on the metal is so curbed and regulated that under it the zinc becomes a picture of sound-waves which, though slumbering in a bed of hard metal, is ready at any time, even centuries hence, to burst forth into the soft cadenzas of word and song, the ripple of laughter, the strains of martial music, as well as the melancholy and imploring drag of the organ-grinder's tuneful melody.

The hydrogen which would otherwise be set free, is neutralized by the well-known depolarizer, chromic acid, and the carrier of the recorded sound-waves is so perfectly and yet so delicately insulated from the action of the acid, that a spiral of sound undulations 600 feet in length, could, without difficulty, be traced and etched on an 8-inch disc, and would represent when reproduced a continuous conversation lasting 7 minutes; all this automatically, and with far greater facility than is possible in making a photograph picture.

In the art of etching, that which insulates the metal from the action of the acid is called an etching-ground, and in the gramophone, this etching-ground is a very delicate fatty film, deposited from the fluid state upon the metal surface. This fluid is made as follows: Into a bottle containing one quart of gasoline, benzine, or petroleum ether, are put 2 oz. of scraped, dark yellow beeswax, and allowed to digest, with occasional stirring, for several hours. We shall then find a clear yellow fluid on the top, and a white cheese-like precipitate at the bottom. The clear fluid is decanted or syphoned off into another bottle, and diluted with the same quantity of gasoline.

When this fluid is poured on an absolutely clean and slightly warmed metal surface, there remains after the gasoline has evaporated, a delicate fatty film, very porous, and so thin that it shines in iridescent colors. It is somewhat tenacious to the touch, but loses its resistance in a remarkable degree when alcohol is poured over it. As soon, however, as the alcohol is washed off with water, the film assumes again its tenacious quality with but very small loss in weight, due to its dissolving slightly in alcohol.

As this etching-ground forms one of the keys to the whole gramophonic art, I will illustrate its qualities by the following experiment:

I have here a strip of zinc, over which the fatty film above described has been deposited from the solution of waxy fat. I have here also a piece of blotting paper, and with its edge touching the film, I now draw several cross-lines on the zinc. Next, I pour alcohol over it and draw a single line over the length of the strip, taking care to touch the surface as lightly as possible. I now wash off the alcohol and plunge the strip into this glass containing a solution of chromic acid, and you will presently see the long line appearing as a dark streak on the zinc, while the cross-lines appear less marked and more reluctantly, showing that the film offered less resistance under the alcohol than without it.

When after about 10 minutes, we take the strip out, we will find under a magnifying glass, that the track of each cotton fibre

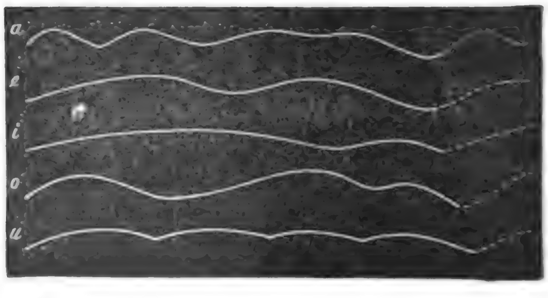

Fig. 2.—Gramophonic Vowel Records.

of which the blotting-paper consists, is sharply etched into the zinc; the rest of the metal has remained entirely untouched. Such is the nature of the etching-ground used in the gramophone for etching sound records.

I will now illustrate how such records are produced, but I would like first to recapitulate briefly what I dealt with at length before the Franklin Institute, relating to the history of the art of making sound-records of the human voice. That dates back to the year 1857, when Leon Scott patented his phonautograph, which is described in every book on physical science. It consisted, as you see on that picture yonder, of a cylinder mounted on a screw, and turned by hand, a barrel-shaped mouthpiece, a diaphragm provided with a damping device, a flexible stylus attached to the centre of the diaphragm, and means for adjusting the position of stylus and record sheet to each other. The cylinder is

1. Paper read before the American Institute of Electrical Engineers, Dec. 16, 1890. Engravings are from the *Scientific American*.

covered with paper smoked with an oily flame, after which the stylus is so adjusted that it presses lightly on the smoked surface. When the cylinder is now revolved, the stylus traces a spiral line on the paper, and when at the same time sound enters the barrel, the diaphragm will vibrate, and the spiral line will assume an undulatory form, according to the nature and pitch of the sound emitted.

Such tracings of sound are called "phonautograms," but since tion of the phonograph, but the technical difficulties which appear in the attempt to bring about the desired result, must have seemed too great to Cros; or he must have gotten discouraged when, later on, seeing the apparently simpler method of the phonograph. At any rate, it appears that he never accomplished what he had conceived with such acute logic, and his paper on the subject (which can be found in the *Comptes Rendus*) was barely noticed, and quickly forgotten.

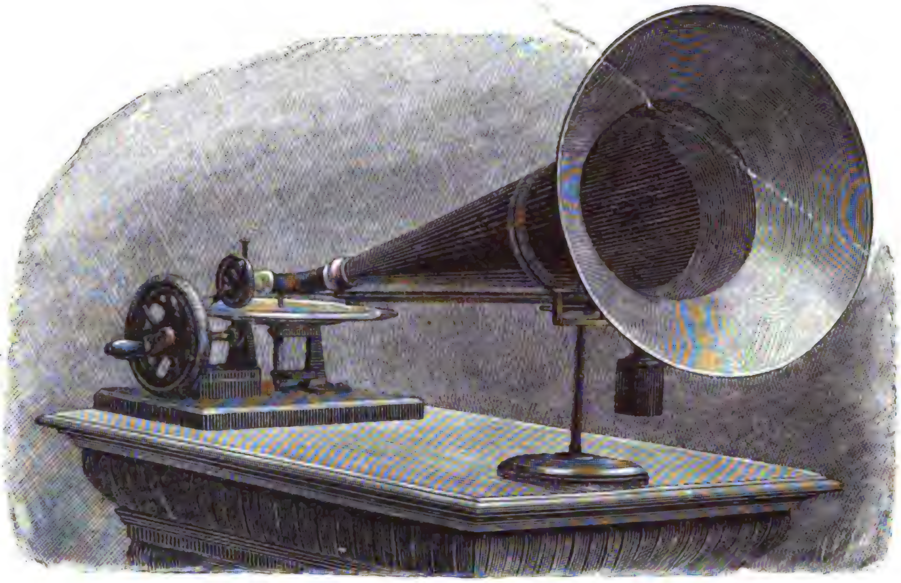

Fig. 3.—Berliner's Improved Gramophne: Reproducing a Record.

I have found that those published as having been made by the phonautograph are not true curves of the sounds they were supposed to represent, I have here some which are more correct, and drawn from gramophone records, representing some of the more prominent vowels, Fig. 2. The waves are complex in character, and between 75 to 150 of these compound waves follow each other per second in the pitch of the ordinary human voice; all of which is well known, and described in the chapters on sound of physical science,

In the spring of 1877, and following in the wake of the invention of the speaking telephone, it occurred to Charles Cros, of Paris, that if such sound-tracings could be engraved, for instance, by the photo-engraving method, and the stylus be then permitted to travel again in the groove or track of these engraved record lines, by revolving the cylinder past the stylus, the original sound would be reproduced. This was about 6 months before the inven-

It was not until after the granting of the patent for the gramophone, that I happened to see a reference to it, and, searching the *Comptes Rendus*, found the article mentioned, which I then translated and embodied verbatim in my paper before the Franklin Institute. While, however, Cros had a correct conception of the general principle of a talking machine, it would have required considerable modification of the rules taught by physical science which were then at his command to obtain practical results; but I will illustrate what he meant, with this model built on the principle of the gramophone.

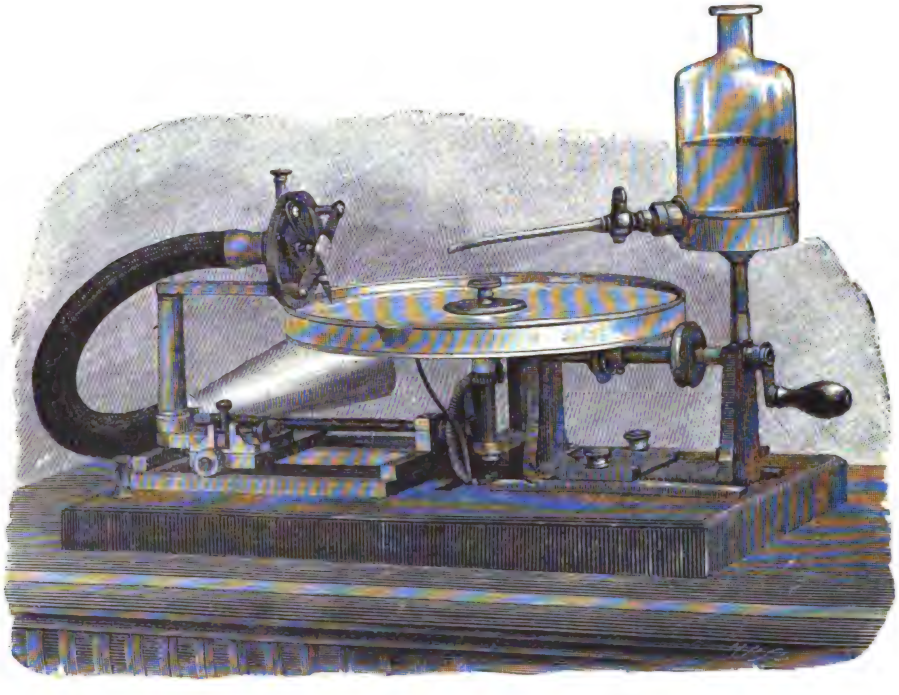

Fig. 4.—Berliner Gramophone—Apparatus For Making Records.

Here is a drum-head of oil-cloth, and across it and pivoted at the top, is an arm or stylus, which is connected to the centre of the drum, and therefore, moves with the latter. The free end of the arm extends beyond the periphery of the drum and carries a brush dipped in ink.

If I now pass a strip of paper underneath the brush and at the

same time move the drum regularly to and fro, an undulatory line of regular character will be drawn on the paper. If I repeat the experiment, but more irregularly, or jerky, the motions of the drum appear marked down as a jerky irregular line.

I now replace the brush by a hard stick and permit it to travel in an undulatory groove engraved in a strip of wood, which strip I draw underneath the stick, and you will see by the reflection of light on the oil-cloth drum-head, that it is moved to and fro by the engraved wave-line, and if these motions should occur rapidly enough, a sound would be emitted by the drum.

This illustrates the general principle of the gramophone. It is, however, in the method of engraving the sound-records that the gramophone departs materially from previous methods, and this I will now show you—Figs. 3 and 4. Here is a disc of ordinary zinc, such as you can buy in every tinshop; it has been polished, carefully cleaned, and has then been coated with our fatty film. I now place the zinc on the turn-table of the gramophone recorder. The turn-table is revolved by a friction-wheel underneath, and connects through gearing with a screw, which propels a carriage across the turn-table, at a slow rate of progression. On this carriage is mounted the recorder proper, namely, a mica diaphragm, across which lies a spring, fastened above and carrying at the lower free end a slender metallic blade, bent downwards slightly, and tipped with iridium, like a gold pen. This blade I now bring down upon the fatty film until it is straightened.

Mounted near the turn-table is a bottle containing alcohol, from which a spout extends to the centre of the turn-table, dropping the fluid upon the fatty film on which I first pour some of it, so as to soak it.

If I now revolve the turn-table, the blade or pen marks a plain line into the fatty film, and as the iridium tip is kept free from the dust-fibres which are continually floating about in the air, and upon the film also, by the presence of the alcohol, the line in proper light appears as a fine silvery streak in the dull fatty surface, showing that the metal is being laid bare by the iridium tip.

If, now, sound enters the tube leading to the diaphram, the atter will vibrate and the line will assume the undulatory form of sound-waves, as before explained.

The gearing of the machine is at present set so that 72 lines are drawn to the inch; but for the ordinary conversational tone, the lines might be twice as close together, without the waves touching. The turn-table revolves at the rate of about 60 times a minute for this size of disc, and if they are smaller, the velocity must be increased, so as not to crowd the waves too close upon one another.

The talking being done, I lift the disc from the machine and dip it in water, which washes off the alcohol, and there is now visible a band of silvery lines in the fatty film. I may now write the date in the central portion of the disc, and press the patent-stamp on it, or add any other remark or signature, all of which will be subsequently etched in, and I may now plunge the disc into the bath of chromic acid. Immediately, the acid attacks the zinc in the lines, and a dark cloud forms over the record, due to the formation of a subchromate of zinc.

While the disc is being etched, let me now turn to the reproducing machine. The principal part is again a turn-table moved by a friction wheel underneath. Above it is an arm pivoted with one end upon a standard having a double or universal motion, and the other end carries the reproducer proper, namely, a diaphragm or mica vulcanized fibre, rubber, or ivory, across which is fixed at its upper end, a stiff spring connected by a post to the centre of the diaphragm, its free end extending beyond the periphery, and carrying a small steel needle which may easily be taken out and replaced when necessary. This pivoted arm is the invention of Mr. Werner Suess, of Washington.

One of the mechanical curiosities of the gramophone is the fact that the etched record itself is the screw which propels the the diaphragm from periphery to centre, for the stylus resting in the groove by gravity or slight pressure, not only is vibrated, but following it and being able to move freely, is led along to the centre and to the end of the etched record automatically. This places the gramophone reproducer in the realm of extreme simplicity, and beyond the necessity of repair under ordinary every-day conditions.

Before proceeding further, I will now let the gramophone show you some of the results of which it is capable at the present time. I should like to remark, that in the present form of the resonator, the sharpness of the effects is somewhat toned down. That this is due to the resonator will become more apparent to you when, later in the evening, you will listen to some of the discs through the rubber ear-tubes. It has been proposed to use a resonator in the form of a large parabolic reflector, so as to enlarge the effects without modifying the timbre. But the effects, although loud, show the natural qualities of the various sounds, and are, in spite of their loudness, neither rasping nor ventriloquistic in quality.

The possibilities of extending the gramophonic principle, are perhaps more noteworthy than its present development. The discs can be easily duplicated, and at the first exhibition in Philadelphia, I showed an electrotype copy of a 12-inch disc which sounded precisely like the original. Since then, I have also succeeded in making talking copies by pressing a matrix into molten glass, but the matrix being [illegible] of copper, the glass used to stick to the form, and warped the glass copy. I am assured, however, that whenever I shall furnish a steel matrix, the perfect copying in glass will be entirely feasible. That such steel matrices can be made is not doubted by those familiar with the art of transferring lines, and then etching the same.

We may then have dinnersets, the dessert-plates of which have gramophone records pressed in them, and which will furnish the after-dinner entertainment when the repast is over. Gramophone plaques with the voices of eminent people will adorn our parlors and libraries.

Very successful copies have been made in celluloid from electrotype matrices, and such celluloid copies are particularly free from all frictional noise, provided the celluloid is pressed hard, and of well-seasoned material. Gramophone records have been printed, and such prints have been photo-engraved, and the copy thus obtained sounded precisely like the original.

Successful copies have been made by letting one disc sing or talk to another one by coupling the recorder to the reproducer by a tube, and turning both simultaneously. In fact, this whole matter of duplicating discs is a department in itself, and would require a separate evening to do it full justice.

The work of gradually bringing the gramophone up to the present state has been exceedingly tedious. Working out telephones or transmitters is child's-play in the face of the traps and Jack-o'-lanterns which beset the experiments with talking machines. The size, form and material of the mouth-piece, the density, length and diameter of the speaking-tube, the size, thickness and material of the diaphragms, the tension, temper and thickness of the springs, shape of the needle points, temperature of the room in which the discs are coated, the quality of the bees-wax, the strength of the acid, and the method of manipulating the sound of voices and of various instruments—all these gave rise to errors and pitfalls, which only continuous repetitions of whole series of tests could locate, avoid, or obliterate.

I have to dwell on these facts, in order to ask your indulgence in not having been able for this evening to cover the important field of copying records—but I have also been disappointed in not receiving a number of celluloid discs, such as are now being made in Germany.

The important subject of good articulation has ever been kept in the foreground, and this is now in so satisfactory a shape that I am carrying on a vocal correspondence with my friends in Europe, by means of small gramophone discs, which can be mailed in a good-sized letter envelope.

Foremost among the feats which the gramophone can perform is the absolute certainty with which it enables people to recognize the speaker's voice, and I could cite a number of instances where persons have been made happy by hearing and recognizing the voices of loved ones whom they had not seen in years, and the owners of which were thousands of miles away.

This whole art is now manipulated with great certainty, and can be learned much easier than the art of photography. Yet, favorably as I believe the gramophone compares with other talking machines, it has barely entered upon the possibilities which lie dormant within its principles, only awaiting the touch of investigation to yield new and important scientific data.

Its advantages at the present time can be summed up as follows:

1. The records are durable, and require a minimum of space for storing.
2. Recognition is perfect.
3. The mechanism of the reproducing machine is a model of simplicity.
4. The records can be printed, and from such prints copies can be made which will sound like the original.
5. The quality of the sounds does not become impaired with increasing loudness.
6. The making of copies is possible by several well-known methods in existing arts.

Lastly, I ought to again refer to the possibilities of enlarging the record lines by the photo-engraving process, and thereby rendering the sounds with increased loudness.

Whatever the art of gramophony represents at the present time, does not consist of accidental results, but the principles and the errors to be avoided are well-known and established, and not a month passes but that new light is thrown on hitherto obscure sections of manipulation, and after three years of work, in which numberless sources of error have been eliminated, the art of etching records has lost none of its attraction, rather fascinating the mind by presenting the possibility of unlimited applications in the service and for the pleasure of mankind.

OPEN HOUSE AT THE ELECTRIC CLUB.

Secretary Price notifies us that the Electric Club will keep open house on New Year's Day from noon on. A buffet lunch will be served, and the Club's silver punch bowl will be replenished as often as is necessary. It is becoming quite the thing to drop in at the Club on New Years for a kindly greeting and a fraternal "send off."

ELECTRICAL UNITS OF THE PRESENT AND FUTURE.[1]

BY PROF. FRANCIS B. CROCKER.

To measure quantities of any kind some unit is needed. In the crude, ancient days the roughest kind of units were sufficient. The length of the king's foot, of a barleycorn, or the side of some temple, or a stone in a pyramid, or something of that sort, were quite good enough for a unit. In fact, nothing better was needed. But as soon as the exact sciences devoloped astronomy, mechanics and other branches of science, and when commerce became more important and definite, the necessity for some more exact unit arose. The rough units I refer to are not only rough, but they are arbitrary. They might just as well select some other king's foot or some other stone in the pyramid, instead of the particular one selected. The more exact requirements of advanced work at first only required definite standards. Therefore the standard yard and the standard quart were adopted, but they were arbitrary. Some person decided what they should be and they were carefully made and deposited in the national archives, and exact copies of those were made and sent around to various points, and they became in some cases the legal standards.

Standards can be adopted by custom or by law. Some of the standards in common use are legalized and some are not. One or more of our most common standards have not been legalized.

So far they had merely arbitrary units. The quart bore no relation to the yard; the yard bore no relation to the second, and neither of the three bore any simple relation to any other unit. That is to say, the fraction representing the relations between the two would have several decimal places. But nevertheless each was definite in itself. The standard yard was a definite length of metal and carefully preserved. Therefore, it was as exact as any unit can possibly be, but it had the disadvantage of having no simple relation to any other unit, and when we pass from yards to quarts and from quarts to pounds, etc., we have no convenient way of translating the quantities. We are obliged to use very awkward figures. What is needed is an *absolute system* in which the units bear exact and easily remembered relations to each other. That is the essence of what is called the absolute system. But it happens that an absolute unit is a very hard thing to obtain. It is impossible to look about and find a standard length that is derived from any source that is unquestionable. It is a matter of judgment and choice, and nothing seems to be very satisfactory for the purpose.

The three facts in nature which are supposed to be absolute, and that philosophers look upon as the three fundamental conditions of existence and thought, are time, space and matter. These three facts are supposed to be fundamental, and everything else is a combination of them.

Therefore, time, space and matter were selected as the fundamental quantities, and it was necessary to find a unit for each.

Taking space or length, which amounts to the same thing, as the first, they began by measuring the circumference of the earth, or, rather, a quarter of it—the earth's quadrant—which is the distance from the pole to the equator. Of course, the actual distance from the pole to the equator was not measured; they measured one degree of it, and calculated from that.

Unfortunately, an error was made that would not be of consequence in anything else, but in the case of a foundation of a system of units it amounts to something—about one one-hundredth of one per cent. Nevertheless, from that measurement the unit was determined. But the question arose, what fraction of the earth's quadrant to take as the unit. Of course, it must be a round number. A ten-millionth happens to be about equal to a yard. A one hundred-millionth would be too small—about four inches. One is a little too small and the other is too large a convenient unit of length. The foot, which is a very convenient unit of length, is between the two, but unfortunately the earth didn't lend itself to this system of units. They chose the larger one, and made the metre the standard of length. The metre is simply one ten-millionth of the earth's quadrant, as measured by the French authorities.

Having the metre, the question was to get a unit of weight. The unit of weight may easily be gotten by cubing—that is, making a volume from the unit of length and filling it with water. But a cubic metre of water would, of course, be too large for a unit of weight, as it weighs about a ton, so a fraction of it was taken. Here again a choice was necessary. A cubic centimetre of water was selected and called the gramme. I think that was a great mistake, because a centimetre is a very small thing and has tended to bring the whole system of absolute units into disrepute. It seems so small that it is not worth considering. I think if they had taken the decimetre, the tenth of the metre, as the unit of length and the cubic decimetre of water as the unit of weight we should have very much better and more harmonious units. A metre is too large and a gramme too small. The unit of time has already been selected. The second is simply the ordinary second that is used in calculating time all over the world and is also a very small unit. Thus we obtain the three primordial standards of length, mass and time, and since, for scientific purposes, the centimetre is taken instead of the metre, we have the centimetre, gramme and second as the three fundamental units upon which is based the C. G. S. system of units. Theoretically, and probably practically, all units of every kind, present and future, can be derived from these three simple fundamental units, which we can all understand and know just how they were obtained and what their values are. The mechanical units are very easily derived from the fundamental units.

There are two fundamental laws of electricity. One is Coulomb's law, which applies to static electricity, and states that a certain charge of electricity attracts or repels another certain charge with a force directly proportional to the product of the quantities and inversely proportional to the square of the distance. The fundamental law of the electric current is that of Ampere, which states that a current affects a magnet in proportion to the strength of the magnet and of the current, the length of the wire, and inversely proportionally to the square of its distance from the magnet. As we can measure the length of the wire and the square of the distance, hence we can get the strength of the current. But this involves having magnetic units. Here are two bar magnets supposed to be exactly alike. If I bring the North poles together they repel each other; and if the magnets were delicately suspended on silk fibres, and brought within a unit's distance and the repulsion between them accurately measured by the torsion of the fibre or by balancing them against some other known force—a delicate spring—then I would find how many units of pole strength the magnet had. To get a unit magnetic field from this we say that a unit pole placed at a unit's distance produces a unit's strength of field. The field is the important thing in dynamo machines and many other practical cases.

To get a line of force, which, by the way, is the unit that is most used in practice, we produce unit field and take a unit's area of it, which is called line of force. It is to a certain extent arbitrary, but it is definite, nevertheless, and that is the line of force that we use so much. We read of it in text books and even in the daily papers.

To return to measuring the current. We take a unit pole and when it has a unit of force exerted on it by unit strength of a current at a unit's distance and a unit length, then it is a unit current. Thus we pass from the quadrant of the earth to the unit of the current by several simple steps, each one of which is easy to understand and each one of which is perfectly logical and follows directly from the previous one.

From current, which is, in my opinion, the fundamental unit of useful electricity, we obtain quantity of electricity. Quantity of electricity is simply the amount of electricity that flows in a unit current for a unit time. Now, electromotive force is about the most troublesome one of these units. It means the tendency for electricity to produce a current and do work. Therefore, electromotive force multiplied by quantity of electricity would give you the work. If I have a certain electromotive force and one unit of quantity I will have a certain work that will be measured by the electromotive force.

Ohm's law gives the resistance as equal to the electromotive force divided by the current, these last two being known. From here on the derivation of the rest of the units is a mere clerical matter. For example, taking capacity as the next unit, we find it equal to quantity divided by potential, that is, the unit of capacity will hold a unit quantity at a unit potential. Work, as I have already explained above, is equal to potential times quantity. Power is rate of work. Therefore, potential multiplied by current, quantity per second, is power.

We come now to self-induction.

Self-induction is somewhat unfamiliar, nevertheless, it is becoming important. Self-induction in telephone work, in aerial, under-ground and submarine lines, dynamo armatures, dynamo field magnets, transformers and other alternating current apparatus, are all practical cases of self-induction. We should consider self-induction almost as much as resistance. We have not done so heretofore, but that is no reason why we should not in the future.

It happens that there are several ways of defining self-induction, but the best way, I think, is to consider it as a counter electromotive force. That is to say, when I send a telephone current through an electro-magnet the latter reacts against the current. When the current tries to go through, the magnet tries to oppose it. Therefore, the best way to define the unit self-induction is to say that it gives a unit counter electromotive force when there is a unit change of current in a unit time. The ordinary way, however, for deriving this unit is to multiply resistance by time. That seems to be an odd way to get it, but what it means is this: That self-induction is the apparent increase in resistance that we get when we try to pass a current through a circuit. But after the current has got flowing, so to speak, then self-induction ceases to exist. It only occurs when a change is taking place.

1. Abstract of an Address delivered before the Electric Club, New York Dec. 18, 1890.

The absolute units have no names, they are simply designated as absolute units of electromotive force, resistance or quantity, as the case may be. This means that they are derived directly from the centimetre, gramme, and second, and "dimensions" of units are mathematical ways of expressing how these fundamental quantities enter each unit. Some of them involve all three of these quantities, some involve two, and some only one. Take, for instance, area. Area is L square; that is, the square of the length; for example, a foot square is an area. Volume is L cube. Velocity is L divided by T. That is, it is L multiplied by T to the minus one power. This enables us to put them all on the same line for convenience.

We come now to the practical units. Every one of these absolute units, derived, as I said, are either so small or so big that they are not useful.

It was necessary to take a certain number of a fraction of an absolute unit. In the case of resistance they took such a number of absolute units in round numbers as would most nearly approach the Siemens unit which had been used before and it happened to be 10^9 absolute units, which means that a billion of these little bits of absolute units will make one ohm the practical unit of resistance, naming it after the discoverer of Ohm's law and establishing the precedent of naming all the electric units after distinguished electrical scientific men, which rule has been followed without exception to the last unit. They call 10^8, that is, 100,000,000 absolute units of electromotive force, a volt, That approximated most closely in round number to the Daniell cell which had previously been used as the unit of electromotive force. They selected the nearest units to the two units already in existence, and having fixed those, theoretical value of the ampere followed. Having arrived at the current absolutely, we can also determine how much metal a current will deposit. But we cannot calculate it absolutely, however; we must determine it. I have here the exact weight of silver that one ampere will deposit from a chloride solution in one hour. It was carefully weighed by the Assay Department of the School of Mines, and it is right to the tenth of a milligramme and weighs 4.0248 grammes. The ampere is a unit that is easily determined. The volt and the ohm required laborious work of years, and the original ohm, as determined by the British Association committee, was about 1¼ per cent. wrong, which is a pretty bad mistake for a scientific measurement.

In making actual standards of these units, the volt is the most elusive one of all. The tangent galvanometer and the silver deposition give up the ampere pretty well, and for the ohm we have a definite coil. But the volt is dependent on standard cells containing chemicals that are very apt to change. They are compounds and they are apt to decompose or change in their composition.

It happens that the unit of capacity, the farad, is a very large unit and we have to take a millionth of it to get a working unit. The microfarad is the standard and it is a pretty good sized standard. It is equal to the capacity of two or three miles of the Atlantic cable. It would contain the same quantity of electricity as two or three miles of Atlantic cable, and it would take a thousand Atlantic cables to equal one farad in capacity. Therefore, you see that what is called the "practical unit" of capacity is very impracticable. The reason the farad is so large is that we have obliged ourselves to define units in terms of one volt, one coulomb, etc. Now, with static electricity, one volt is very small. Our ordinary static charges are 100,000 volts or more; for instance it takes about 100,000 volts to spark one inch.

I would like to point out the fact that we have "absolute units" and "practical units," so called. I put both of these in quotation marks. Absolute units, as I have said, are not absolute, they are based on an arbitrary dimension of the earth incorrectly measured. Now, practical units in the same way, are not practical, because we have one, the farad, that is 1,000 times greater than the greatest practical capacity in existence. Therefore, I maintain that we must have a third system of units and that is the "working" units. You could call them "commercial," but the objection to that is that they are equally used in the laboratory as in commercial work. We use a microfarad in the laboratory the same as in the office of a telephone or cable company. Therefore, they are not, strictly speaking, commercial, but they are *working* in both cases. Sometimes the working units agree with the practical and sometimes they do not. The ampere, coulomb and volt are the same, although in telegraphy we use the milliampere. Then we come to the ohm. That is, the ohm is right for most practical work, but for insulation tests we have to use a megohm. Nobody thinks of giving insulation tests except in megohms. Therefore, for that class of work, the working unit is the megohm and not what is called the practical unit.

When we come to the microfarad, there is no question. The practical unit ceases entirely to be practical, and we have to adopt the working unit which is almost infinitely different.

The watt is a convenient unit for a great many purposes, but when we use it for large work we use the kilowatt, which, by the way, is a good way of rating dynamos, because it is fairly near a horse-power.

Then we come down to the last of all—the henry, the new member of the family, and it is a question whether the working unit will be a henry or a millihenry. I did think of reducing the value of the henry to $\frac{1}{1000}$ of its value as given in the table; but it would have been a mistake, for the reason that, instead of having its value one second multiplied by one ohm, we would have its value a second multiplied by a thousandth of an ohm or a hundredth of an ohm. That would be destroying the simplicity and the harmony of this system—a feature which it certainly does possess. Every one of these units is derived from every other one in the simple ratio of one to one, and in no case is there any complex relationship of a thousandth or ten-thousandth or anything of that sort. You see that the coulomb is an ampere multiplied by a second, a volt is one ampere multiplied by an ohm, a farad is a coulomb divided by a volt. A joule is a volt multiplied by a coulomb, and a henry is a second multiplied by an ohm; and to make any one of them variant, would I think, be a mistake, particularly as it would have been the only exception to the harmony of the system.

Fortunately, the henry approximates a practical value. For example, a large Edison dynamo, shunt wound, will run up to one or more hundred henrys. A telephone magnet will be between $\frac{1}{100}$ and $\frac{1}{10}$ of a henry. We could not expect that to be a very large value. An ordinary relay is several henrys in value. A large induction coil is often 1,000 or more henrys in value. Therefore, there is nothing preposterously small or large about the henry. It is about right. I have given in the last column of the table the actual or experimental value. That is, 4.025 grammes of silver per hour is the ampere. The volt is .926 of a Daniell cell. The legal ohm is 106 centimetres of mercury one square millimetre in cross section, etc. The unit of self-induction is equivalent to the length of the earth's quadrant. Thus we see that often starting with the earth's quadrant in this system of units, to obtain the fundamental units of length, and passing through all the mechanical units and the electric units, we finally get back to the earth's quadrant again. It is certainly quite remarkable and striking. It is a fact, nevertheless, that the unit self-induction is properly represented by a length equal to the earth's quadrant. In fact, it has been called the quadrant and was so called by the Paris Conference, which, I think, was a great unfairness to American electrical men, both living and dead, because certainly America's contributions to electrical science and industry have been fully equal to those of any other county, and if England has the farad, joule and watt, named in honor of her distinguished electrical scientists, if France has the coulomb and ampere, if Germany has got the ohm, and if Italy has got the volt, I think it is certainly not unreasonable for us on this side of the Atlantic to ask for one unit, to be named after the discoverer of self-induction, Joseph Henry.

In regard to future units, which the requirements of advanced work will soon necessitate, we need a unit of the strength of a magnetic field. We can express it as so many lines of force to the square centimetre, etc., but that is a very clumsy way. If we simply called it one Franklin, it would be very preferable to a long sentence. We all have in mind the naming of some electric unit after Franklin, but, unfortunately, Franklin is not identified with magnetic work. He is identified with electrostatic work, but all the electrostatic units have been named. But, perhaps, his name may be adopted.

This treatment of units is necessarily superficial and all I have attempted to do is to show you the general derivation of them, starting with the very first conception and coming to the present time and a little beyond.

DETERIORATION OF ELECTRIC RAILWAY RETURN CIRCUITS.

President D. F. Henry, of the Federal Street and Pleasant Valley Railway Co., Pittsburgh, has been complaining of the rapid deterioration of the return conductors of that road. He says that they may have to adopt an overhead return conductor, owing to the rapid deterioration of the underground connecting wires in the peculiar soil of Pittsburgh. A striking fact is noted in connection with the return conductor leading from the track rail to the negative poles of the generators. This is a large insulated wire, and that portion which is laid under the floor of the power house is encased in a wooden box or trough, while under the sidewalk about six feet from the rail it is embedded in the soil. On cutting through the insulation recently that portion of the conductor laid in the soil was found to be almost destroyed, while the section in the wooden casing was, apparently, as good as new.

THE PRESIDENT'S MESSAGE.—The Western Union Telegraph Company handled the President's message and furnished it gratis to the press of the country as a compliment to the press and the people. It contains about 14,000 words.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

METHODS OF TESTING TRANSFORMERS.

[152.]—Dr. Louis Duncan in his letter (147) to THE ELECTRICAL ENGINEER, December 3, 1890, p. 627, refers to the disposition which he thinks certain recent investigators have shown "to claim as original in 1890, a method which was not new in principle in 1887,........."

Whether there is anything in the papers of Mr. Ryan, of Messrs. Humphrey and Powell, or of Messrs. Tobey and Walbridge to warrant Dr. Duncan's remarks, readers must judge for themselves; but I desire to say that it was not the purpose of any of the students of alternating current phenomena at Cornell, to put forth *claims* of any kind. Their sole purpose was to describe certain sets of measurements. Mr. Ryan's first paper, although entitled "Transformers" was in fact a study of a *single* commercial transformer, under conditions commonly met with in practice. The work of Humphrey and Powell was supplementary to that which Messrs. Ryan and Merritt had done. The paper of Tobey and Walbridge did not deal with methods of testing alternating current dynamos, but with certain interesting peculiarities in a new type of machine.

The absence of any attempt at historical review, even in these papers of narrow and definite scope, is, in my opinion, to be regretted; but the authors have followed a pretty well established precedent, so far as the publication of papers of the class in question is concerned, as any one may easily convince himself of by glancing through the *Transactions* of the American Institute of Electrical Engineers, and to ascribe the omission to an unworthy motive, is unjust.

The expression from Humphrey and Powell which Dr. Duncan quotes, and to which he takes exception, is incomplete. That portion of the sentence which he has omitted to quote in his letter, indicates clearly enough that it was not to the method which Dr. Duncan has characterized as "not new in principle in 1887," that Humphrey and Powell refer, but to a modification of it. The modification was one which made it possible to get "true instantaneous values of E. M. F. and current in forty-five minutes." The importance of this modification is a matter of opinion. Dr. Duncan deems it insignificant. Had he had the opportunity of putting the Ryan electrometer to the test and of comparing its performance in this kind of work, with that of the Thomson quadrant electrometer, he might perhaps have found the opinion of Humphrey and Powell that an important step in the matter of transformer tests had been taken within the year, not altogether unwarranted. The relation of the methods used by Mr. Ryan and his co-workers, to those of an earlier day, of which they were, of course, as in all such cases, a development, is a matter of history. What fragment each investigation adds to the sum of human knowledge the future will determine. In the mean time should there be cause for anything but sincere satisfaction in the fact that the investigations of Duncan, Hutchinson and Wilkes in 1887, and of Searing and Hoffman of the Stevens Institute, in 1889, have met with complete corroboration through the work of the still later observers? EDW. L. NICHOLS.

CORNELL UNIVERSITY, Ithaca, Dec. 18, 1890.

TRAIN ELECTRIC LIGHTING.

A new electric lighting system for railway cars is to be placed on the market some time during the year 1891 by the Consolidated Car Heating Co. Each car will have an independent source of light which will be available even when the car is at rest for five hours, or perhaps longer. The tax upon the motive power will be slight and indirect, no steam being used. The designers are now endeavoring to so simplify and cheapen the apparatus that it shall be, both in first cost and in running expense, more economical than any lights now used in first-class cars. The system will include storage batteries and a dynamo on each car, driven from the car axle.

ABANDONING CABLES FOR ELECTRICITY AT GRAND RAPIDS, MICH.

Director Hagar, of the Grand Rapids Consolidated Street Railway Co., which has a million dollar cable system, says that they will put in probably 45 miles of electric road next year. They have 14 miles of cable road which will be abandoned, the cable cars being replaced by electric cars, and overhead wires being strung above the present cable tracks. It is said to be likely that the Short system will be used.

EUROPEAN CORRESPONDENCE.

LONDON.

Electrical Underground Railway.—Provisional Orders.—Paper on Insulation.—Paris Telephones.—Obituary.—Royal Society.—Hamburg.—Prof. Ewing.—Overhead Wires.

THE Austrian Minister of Commerce has sent two engineers to study the new underground electric railway in London.

The time limited by the Board of Trade for receiving applications for provisional orders to be considered for 1891, expired on the twenty-eighth of November. I am informed by a creditable source, that no fewer than seventy-six separate orders will be applied for, of which seventeen seek power to light various portions of London and the suburbs. I think the greater number of applicants will be found to be companies, but as few will be opposed, the next twelve months should see a rapid development in town lighting.

An interesting paper was read before a recent meeting of the Berlin Electro-Technical Society by M. Grawinkel. The subject taken was the condition of underground mains belonging to the Administration of Posts and Telegraphs of the German Empire. In contrasting the results of tests taken during 1889 with those of former years the author concludes that the insulation of newer cables is much inferior to that of older cables. This is due to the inferior quality of gutta percha now employed, consequent on the enormous demand for the material.

After this week Paris telephone customers will be treated very liberally by the Telephone Department. For a sum equivalent to 10 cents a person may transmit a message to the central bureau of 100 words and a special messenger will convey it to the desired destination.

The plan for an electric street railway in Karlsbad, which is to go from the railway station into the town, has been passed and next summer, in addition to electric lighting, a tramway operated electrically will be working.

M. Bede, a prominent Belgian electrician and engineer, died this week. He was one of the leading members of the Brussels Polytechnic School and successfully carried out many important electrical installations in Russia and Italy.

The annual meeting of the Royal Society was held on Monday. In the course of his remarks the retiring president (Sir G. Stokes) said that the Society had received from the Joule Memorial Committee £1,400. Medals were awarded, one of the recipients being Dr. Hopkinson. At the dinner in the evening the new president Sir Wm. Thomson, occupied the chair, and proposed the health of the medalists and the visitors, among whom was Prof. Hertz. In the speaker's opinion Dr. Hopkinson's researches in magnetism and electricity affected the whole range of physical science, while Dr. Hertz's work in electro-magnetic radiation was of an epoch-making character. Dr. Hopkinson in responding spoke of the assistance foreign governments gave to their scientific men in making researches He said deliberately that if he had been obliged to obtain the sanction of the English Government Department to make experiments or make them in a licensed place, very little work would have been done, and he should not have been in the proud position of one of the medalists that evening.

The Hamburg authorities have granted £15,000 for an electric light installation and for structural improvements in the Hamburg Stadt Theatres.

It is proposed by a German firm to conduct experiments on the Finow Canal with electric launches.

One of the greatest authorities on English tramways from a financial point of review in a monthly report says there is a good time coming for holders of tramway shares and that is when electricity operates their lines. He considers there will be a complete revolution in the finances.

Prof. Ewing has succeeded Prof. Stuart in the chair of engineering at Cambridge.

We are likely to have some hard fighting over the subject of overhead lines. Last week memorials were submitted to the Board of Trade calling attention to clauses which were unnecessary and likely to retard the spread of electric lighting. The rules on which the Board works were framed by the Council of the Institution of Electrical Engineers, and it is argued with apparently some reason, that the framers were not practical men. The rules stickle for heavy insulation and other conditions which will have the effect of rendering electric lighting too costly, if persisted in. At the present time, the lighting carried out at Farnham and Chelmsford is against the rules. It will be interesting to see how the rules are to be enforced.

Many of the principal streets are up and mains are being laid, much to the annoyance of shop-keepers and pedestrians.

CORRESPONDENCE.

BOSTON.

Visiting Baltimorians.—The Snow Storm.

The mayor and city council of Baltimore visited Boston last week, as the guests of the North Avenue Street Railway Company of that city, for the purpose of inspecting the electric car system of the West End Street Railway Company. The party made a trip in the electric cars to Grove Hall, where the car station was inspected. From there they were taken to the central power station of the West End Company on Albany street, where an hour was pleasantly spent. In the evening a dinner was given at Young's Hotel, at which Capt. Eugene Griffin, of the Thomson-Houston Electric Company, presided. The following day was spent in visiting the factories of the Thomson-Houston Company at Lynn.

At the time of writing, a very severe snow storm is raging, probably the severst storm since the introduction of the electric car system. Up to the present, however, the electrics appear to be buffeting their way quite successfully with the snow, though it is already many inches deep. It may beat them yet, if it goes on.

BOSTON, December 26, 1890.

CHICAGO.

Testing the Interior Conduit System.—A Station That Had No Interior Conduits.—The South Side Elevated Road.—Killed by Shock.—Cheap Aluminum.

THE Illinois Chapter of Architects assembled at No. 65 Washington street last week to witness some tests made by the Interior Conduit and Insulating Company, of New York. A set of nine tests of possible combustion from electrical wires were made and examined by Chief Swenie, Prof. Barrett, Messrs. Haskins and Borden, with various members from the Board of Fire Underwriters. The results obtained were highly satisfactory. The tubes of the Interior Conduit & Insulating Company are now being very largely used for inside wiring all over the country on account of their many advantageous features, and they are also being introduced for underground work, one notable example being on the street railway at Minneapolis, where bare conductors are drawn into them, something hitherto unattempted with the ordinary forms of conduit, and are in all cases giving good success.

The Eldorado Gas and Electric Light Works were burned to the ground last week, leaving the town in darkness. The loss is estimated at $5,000, with no insurance.

The South Side Alley "L" road is negotiating an important deal with L. Z. Leiter for a tract of land fronting on Van Buren street, 40 x 80 feet, adjoining the new Leiter building. The land is near the northern terminus of the road, and it is stated that if arrangements are carried out either for a purchase or a long-time lease the "L" road will erect a new building for the general offices and the electric power house of the company. The agent of the company states that they have not yet called for any plans or specifications for a new building, and will not do so until they have located the site definitely. The work on the road is going forward in a very gratifying manner, and cars are expected to be running by May next if the same success in the future is attained as recently in securing right of way.

George Winn, superintendent of the Fire Alarm Telegraph of Allegheny City, fell from a telegraph pole last week and was instantly killed. He was repairing a wire and it is alleged received a shock, as a long burn was discovered on his body. When picked up it was discovered that his neck was broken by the fall.

Among the uses for aluminum suggested by Mr. Eugene H. Cowles, president of the Lockport company, in a recent interview are the following: At 50 cents per pound the new metal will compete with copper at 17 cents, the latter being 3.56 times as heavy as an equal bulk of aluminum. But the electrical conductivity of aluminum that is 98 per cent. pure is only 75 per cent. that of copper, so that one-third more area would be required to do the same work. A reduction of 45 per cent. in weight of motors for electric cars can be secured by using the new metal, which in itself is no small advantage, seeing that the latter promise to come into extensive use in the near future. The coating and lasting qualities of aluminum far surpass those of tin, and it will cover three times as much surface for equal weights, making it necessary to sell tin at 16 cents per pound in competition with the other at 50. Nickel at 70 cents would no longer be used for plated ware or coinage, the new metal being much cheaper and cleaner. He expects to see it sell at two to three hundred dollars per ton, and at these figures it will be the cheapest metal next to iron and steel. The price must fall lower and lower as the facilities increase for making the material, and the market adapts itself to the absorption of larger quantities of the new metal.

CHICAGO, Dec. 24, 1890.

REPORTS OF COMPANIES.

THE WESTINGHOUSE LOAN.

A special despatch from Pittsburgh of Dec. 26, says: "A meeting of the bankers and business men of this city who had loaned George Westinghouse $500,000 lately was held to-day. An advisory board of five were selected to act with Mr. Westinghouse in placing the half million and managing the affairs of the companies requiring the loan. Of the gentlemen present at the meeting seventeen banks and 30 business men of the city were represented, who had furnished the emergency loan from $2,000 to $35,000 each. At the meeting Mr. Westinghouse presented a statement of his interests as follows, the two first named being those requiring the half million loan: Westinghouse Electric and Manufacturing Company—Capital issued, $6,500,000; gross receipts, $5,000,000; net receipts, $500,000; accounts receivable, $1,436,000; material in stock at cost, $780,000; other than bonded debt, $3,339,900; Philadelphia Natural Gas Company—Capital issued, $7,500,000; gross earnings, $3,000,000; net earnings, $1,500,000; bonded and other debt, $1,990,000; accounts receivable, $700,000; material at cost, $800,000. Totals of all Westinghouse interests, comprising eight companies, among them the air brake company: Capital issued, $23,170,000; gross earnings, $16,550,000; net earnings, $4,205,000; bonded debt, $1,059,000; other debts, $6,257,900; accounts receivable, $6,297,147; material at cost, $2,560,000. In an interview one of the subscribers to the fund stated that Mr. Westinghouse was negotiating the half million loan in the East when his competitors in business prevented it. The loan was merely being made to tide over the present stringency, as the statement would show."

It is stated that Mr. Bannister, who is already associated with the Westinghouse interests in Pittsburgh, has been appointed general manager of the Westinghouse Electric Co.

DIVIDENDS.

THE MEXICAN TELEGRAPH COMPANY has declared a dividend of 2½ per cent. for the quarter ending Dec. 31, payable Jan. 7. The statement for the quarter shows a surplus above charges and dividends of $36,828, and a total surplus of $167,698. The Central & South American Telegraph Company declares a quarterly dividend of 1¾ per cent. for the three months ending Dec. 31, and made the same payable Jan. 7. The surplus for the quarter is $19,551, and the total surplus is $324,085.

MIDDLETOWN, CONN.—The Middletown Electric Light Co. have declared a 2 per cent. dividend.

BANGOR, ME.—The Bangor Electric Light & Power Company have declared a dividend of 15 per cent., covering 1888 and 1889, payable Jan. 1, 1891. This will leave a surplus of about $8,000, and the company has voted to pay semi-annual dividends of 4 per cent., commencing July 1, 1891.

STOCKS AND BONDS.

CHICAGO, ILL.—The Sunbeam Incandescent Lamp Co., of Chicago, have filed a certificate of increase of capital stock from $30,000 to $100,000.

DETROIT, MICH.—The Detroit Electrical Works have increased their capital stock to $500,000, and the issue has been eagerly subscribed for. The works are now rushed with an immense influx of orders for the popular Rae electric railway system.

TORONTO, CAN.—A new telephone company has been organized with a capital stock of $250,000.

HOLYOKE, MASS.—The stockholders of the Holyoke Street Railway Co. have voted to increase the capital stock from $50,000 to $150,000 so as to equip its several lines with electricity in the spring.

MILWAUKEE, WIS.—An issue of $2,000,000 of bonds will soon be made in order to equip the street railroads with electric power.

BOSTON, MASS.—The net earnings of the Thomson-Houston Co. for the year to end February, 1891, will, it is estimated, reach $3,370,000.

BUFFALO, N. Y.—The Bell Telephone Co., of Buffalo, has filed a certificate showing an increase of its capital stock from $800,000 to $1,000,000.

ALPENA, MICH.—The Alpena Electric Light Co. has increased its capital stock to $84,000, and will put in an incandescent plant.

BURLINGTON, VT.—The Vermont Electric Co. will increase its capital stock to $100,000 by issuing $35,000 of 7 per cent. guaranteed stock and $40,000 of second preferred 4 per cent. stock. The object of the company is to utilize the big water power above Winooski village and transmit it electrically to Burlington for light and power. E. I. Garfield is president, and W. S. Vincent and W. H. Lang, directors.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DEC. 23, 1890.

Alarms and Signals :—

Fire-Alarm Box, J. J. Ruddick, 443,183. Filed Sept. 13, 1890.

A fire-alarm box, with clock mechanism in which a single lever for winding the clock mechanism is employed also for releasing a detent through one and the same movement.

Fire-Alarm System, F. T. Feary & J. Speleber, 443,478. Filed July 30, 1889.

A fire alarm system designed to enable private stations, other than the regular stations of the system, to send in an alarm directly to a fire-engine house in advance of regular alarm, and providing means whereby such private signal box controls the regular signal box so far as to prevent the interference of signals. The private signal box has a direct wire to the engine house.

Clocks :—

Electro-Mechanical Central System for Regulating Clocks, C. A. Mayrhofer, 443,291. Filed Dec. 29, 1888.

Claim 1 follows:

The combination, with a number of subscribers' lines extending from a central office, of a switching apparatus at the central office, a motor for operating said switching apparatus, a releasing device for said motor, and electro-magnet located in the circuit of the master-clock and adapted to actuate said releasing device so as to start the motor clocks at the residences or offices of the subscribers, devices on said clocks for switching them into the subscribers' lines, hand-setting devices on said clocks, and means for operating said hand-setting devices when the subscribers' clocks are switched into circuit with the main switching apparatus.

Conductors, Conduits and Insulators :—

Insulator, W. L. R. Emmet, 443,174. Filed Sept. 18, 1890.

A line insulator especially applicable to electric railway work. Designed for simplicity and strength and with a view of supporting the weight of the wires by strains of compression rather than by tensile strains.

Electric Insulator, F. Bain, 443,187. Filed March 25, 1890.

A design for insulators of the "petticoat" type usually made of glass or porcelain. The petticoat portion has formed upon its outer and inner surfaces a continuous series of separate circumferential sharp ridges, designed to prevent the formation of a continuous film of moisture.

Distribution :—

System of Electrical Distribution, H. A. Rowland & L. Duncan, 443,181. Filed Sept. 10, 1888.

A system of distributing continuous currents of high potential and reducing the potential at points of use, or further distribution, through the employment of secondary batteries as tension reducers. A number of secondary batteries are provided with a continuously operating commutator, by which the connections of the battery are changed, so that such batteries are alternately charged in series by the high-tension current and discharged in a current of low tension on the consumption or translation circuit. Provision is made that neither the charging nor the discharging circuit is ever broken; both are always continuous. This is accomplished by dividing the batteries into sets, and by using upon the commutator over-lapping contact surfaces, so that before the circuit of any one set is broken the circuit of another set is closed.

Dynamos and Motors :—

Machine for Dressing the Commutators in Dynamo-Machines, G. P. Cummings, 443,270. Filed April 18, 1890.

Claim 1 follows:

The combination in a machine for dressing the face of dynamo commutators, of a spindle, an encircling sleeve rotating thereon, a second sleeve sliding longitudinally upon the first and having a spline and groove connection therewith, a grinding or abrading wheel fitted upon said sliding sleeve, means, substantially as described, for attaching the spindle to the dynamo in parallelism with the commutator, and an adjustable gear for connecting the rotating spindle with the dynamo, whereby the two are made to revolve in unison.

Dynamo-Electric Machine, C. P. Scheuritzel & J. L. Hess, 443,407. Filed Feb. 5, 1890.

The invention consists chiefly in the method of winding the armature coils and placing them in position, and includes an arrangement of a plurality of brushes on the commutator for connecting with one or more of the commutator bars for the purpose of varying the current to requirements. The machine is particularly adapted for furnishing a variable current of a constant potential. The coils are wound in the form of an irregular hexagon, with long and short sides diagonally opposite each other and with parallel sides, forming the active portions of the coil, diametrically opposite each other. In one method of winding employed the armature is formed of a series of coils wound one through the other, the coils being thus linked together and forming an endless chain.

Galvanic and Thermo-Electric Batteries :

Galvanic Battery, H. J. Brewer, 443,219. Filed June 16, 1890.

Improvement in the type of batteries known as "dry batteries." The invention includes the combination of a carbon cylinder and a zinc cylinder concentrically arranged and having their open ends embedded in a sealing body of insulating material; an exciting material consisting of a compound of sulphate of lime, chloride of zinc and glycerine; also the combination of a body of solid or semi-solid exciting material and an absorbent material containing moisture.

Lamps and Appurtenances :—

Electric Street-Light, G. M. Kim, 443,097. Filed May 19, 1890.

A design and construction of a mast-arm for electric street lights.

Electrical Signaling Apparatus, A. B. Wyckoff, 443,157. Filed May 5, 1890.

The invention consists in devices for flashing an electric light for signaling or other purposes. For a lamp or group of lamps there is provided a rotating shaft having projecting arms in different planes, and segments, one for each arm, one segment serving to direct the current to the lamp or lamps and the other segment shunting the current back to the dynamo. The object is to flash the lamp instantly up to its full power and to extinguish it instantly.

Circuit Breaker and Closer, J. S. Potter & D. J. Cartwright, 443,404. Filed Aug. 16, 1890.

Design and construction of circuit-breaker and closer particularly adapted for the key-sockets of incandescent electric lamps.

Gas and Electric Light Fixture, C. Felton, 443,487. Filed Dec. 28, 1889.

A device for securing the canopy of a gas or electric light fixture in position through frictional contact.

Medical and Surgical :—

Electric Belt, J. L. Pratt, 443,226. Filed May 6, 1890.

An electric belt with a battery case at the wearer's back; the elements of the battery are joined by hooks and eyes.

Metal Working :—

Electric Welding Apparatus, H. Lemp, 443,224. Filed Aug. 6, 1890.

Improvement in the class of apparatus in which movement is given to the work while heated during the welding, upsetting or other operation. Avoids employment of sliding contacts between the clamps holding and moving the work and the contact pieces or electrodes connected with the source of current, by bringing the current bearing electrodes directly in contect with the work and moving the work by means independent of the electrode.

Claims 1 and 10 follow:

1. In an electric metal-working apparatus fixed current-bearing electrodes making contact with the work and through or by which the work slides in the welding, upsetting, or other operation, as and for the purpose described..

10. In an electric metal-working apparatus, the combination as substantially described, of a number of current-carrying electrodes consisting of reciprocating plungers operating in lines converging upon the work and adapted to make sliding contact and means for rotating the work while the plungers make rubbing or sliding contact therewith.

Electric Cash-Register, W. L. Bundy, 443,475. Filed Sept. 30, 1889.

Claim 1 follows:

The combination with a rotating multiple switch and contact fingers engaging therewith and push buttons arranged in decimal sets electrically connected at will to the fingers, of an electro-magnet and its armature, adapted to release the switch when the circuit is made by operating a button and to lock it when the circuit is broken by the rotation of the switch.

Miscellaneous :—

Cut-Out, G. W. Mingle, 443,195. Filed Aug. 1, 1890.

A safety device for telegraph, telephone or other wires to protect them against damage from contact with electric lighting or other powerful currents, or against lighting. It is an electro-magnetic apparatus for opening the circuit to be protected upon contact with a circuit carrying a too powerful current, and provided with an additional, or auxiliary, armature for the purpose of making a ground connection.

Apparatus for Painting Electric Wires and their Coverings, R. W. Heppell, 443,237. Filed Jan. 23, 1890.

A painting or coating machine, having brush-holders arranged to hold brushes in a radial position around the wire which is fed through the machine.

Electrotype, E. H. Hanson, 443,278. Filed June 11, 1889.

An improvement in the backing and blocks of electrotypes. Backing is of a different metal from the electrotype, say lead, the block is provided with grooves to receive tongues formed in the backing.

Electric Safety Device for Elevators, H. E. Holmes and C. F. Grosvenio, 443,283. Filed April, 14, 1890.

A device, including electro-magnetic apparatus, for insuring the automatic stoppage of a moving elevator when a condition of danger arrises through derangement of the machinery.

Electric Safety Device for Elevators, H. E. Holmes and C. F. Grosvenio, 443,282. Filed March 26, 1890.

An electro-magnetic device adapted to stop the motion of an elevator in transit on the occasion of the projection of any part of the person of a passenger or of any object or article on the car or platform across or beyond the floor through which the hoistway passes, or the projection of any object on one of the floors into the hoistway.

Recording Pressure-Gauge, J. B. Edson, 443,360. Filed June 12, 1890.

Claim 7 follows:

The combination, with the indicating and recording mechanism and the alarm bell and electrical appliances for operating the same, of a circuit-closer included in the circuit of said electrical appliances, and consisting of a rod connected to and actuated from the indicating mechanism, a stationary contact to and from which said rod moves, and a spring-support in which said contact is adjustably mounted.

Watchman's Time-Recorder, I. D. Fuller, 443,435. Filed July 2, 1890.

Electro-magnetic apparatus employed for operating the type-bars in a watchman's time-recorder.

Railways and Appliances :—

Electric Railway. E. M. Bentley, 443,084. Filed Apr. 9, 1887.

A system of conductors and contacts for conduit electric railways. It comprises an insulated main-supply conductor with exposed contacts at intervals, a shallow sectional metallic channel or conduit open at the surface of the street, and a contact-conductor traveling along the channel in electrical connection with both the exposed contacts of the main-supply conductor and surface conduit. The surface conduit is formed in sections insulated from each other. The traveling conductor attached to the car is in the form of a rod or wire-rope and is of a length greater than the distance between the exposed contacts of the main supply conductor.

Railway-Switch-Operating System, S. L. Powell, 443,149. Filed July 5, 1890.

Electro-magnetic mechanism for controlling the operation of switches automatically from or by a passing train or from a main station or office.

Electrically-Operated Railway-Switch, S. L. Powell, 443,167. Filed Feb. 21, 1890.

The switch bar and switch-bar actuating mechanism are set in motion and locked in given position by electro magnetic apparatus.

Mounting for Electric Motors, A. L. Riker, 443,227. Filed Apr. 23, 1886.

A mounting for motors upon cars or other vehicles.

Claim 1 follows:

A mounting for the propelling motor of a vehicle, comprising in combination a supporting frame or carriage pivoted on one of the axles, springs bearing on a portion of said frame or carriage and pressing in opposite directions, and chains arranged to limit the motion of said frame or carriage and to support the same in case of breakage of said springs, substantially as described.

Electric Railway, R. M. Hunter, 443,451. Filed Sept. 1, 1890.

A system of conductors combining overhead and surface conductors. The overhead conductor is preferably the positive and the surface or underground conductor the negative. The inventor prefers to make the surface working conductor into sections arranged upon the road surface and combined with an imbedded supply conductor and automatic switches for connecting the supply conductor with the sections of the surface working conductor in connection with one of the collectors of the motor or car.

Electric Railway, R. M. Hunter, 443,442. Filed Sept. 5, 1890.

A system of conductors consisting of two suspended bare conductors, arranged one above the other, the car or vehicle carrying two trolleys or collectors. Two insulated supply conductors are connected at intervals with the working conductors.

Printing-Telegraph, S. V. B. Essick, 443,134. Filed Nov. 7, 1888.

Improvement upon printing telegraphs, of the class printing in lines upon

a page, previously patented to the same inventor. Objects of the present invention are:—Adaptation to closed circuits; to release the paper carriage at any point of its forward progress; and improvements in pole-changing devices.

Claim 1 follows:—

In a printing telegraphic receiver, a type-wheel driven by a train of gearing, a paper carriage having advancing and restoring mechanism, and a releasing device mechanically connected to one of the gear wheels for automatically releasing the paper carriage at any point of its excursion, substantially as described.

Printing-Telegraph, S. V. B. Essick, 443,135. Filed March 10, 1890.
Further improvement of the same inventor's system. Present invention directed chiefly to details of the paper carriage mechanism.

Printing-Telegraph, S. V. B. Essick, 443,136. Filed July 5, 1890.
Further improvements of the same inventor's system. Embraces modifications of transmitting apparatus and of the printing receiver.

Telegraph Transmitter, S. W. Smith, 443,381. Filed June 2, 1890.
An apparatus for the mechanical transmission of Morse characters through the manipulation of a key-board similar to those employed in printing telegraphs.

Secondary Batteries:—

Electrode for Secondary Batteries, I. Kitsee, 443,454. Filed Feb. 11, 1890.
The electrode consists of active material in the form of a perforated plate, held in a containing frame made of rubber or other material unaffected by electricity or the acid of the electrolyte.
A suitable conductor is embedded in the active material.

Electrode for Secondary Batteries, I. Kitsee, 443,455. Filed Feb. 11, 1890.
Substantially similar to number 443,454 above.
The conductor embedded in the active material is led out through the joint of the rubber containing band which is riveted at one corner of the electrode.

Secondary Battery, I. Kitsee, 443,456. Filed Feb. 11, 1890.
A modification of the electrodes of the above two patents; the active material of the electrode, consisting of a series of blocks or plates placed edge to edge with strips of conducting material between and the whole clamped in an adjustable frame of rubber or other unsusceptible material.

Secondary Battery, I. Kitsee, 443,457. Filed Feb. 17, 1890.
Battery consists of electrodes, both positive and negative constructed on the methods shown in the above three patents of the same inventor.

Telegraphs:—

Printing-Telegraph, F. B. Rae, 443,111. Filed Aug. 9, 1888.
Adaptation of transformers to the transmission of telegraphic signals from a central station to a number of sub-stations, as in stock-reporting systems. It relates to those methods of transmission which employ upon the lines impulses of alternate polarity, and in which such currents must be capable of being arrested at any stage in order to produce the desired signals, usually requiring a prolonged current of the sign last flowing. The special object of the invention is to facilitate transmission through a considerable number of separate circuits from one transmitting machine. The primary of transformer is connected to the transmitter; the actuating magnets of a number of pole-changers, one for each line, are connected with the secondary of the transformer in multiple arc. The potential of the current from the transmitter is suitably reduced by the transformer.

Telephones and Apparatus:—

Telephone Circuit and Apparatus, J. L. McQuarrie, 443,145. Filed June 27, 1890.
Provides a metallic telephone circuit which may be common to a number of subscribers; in which each subscriber may at all times have the use of a metallic circuit and in which each subscriber may be called from the central station without giving an alarm at another station, and may also signal the central station without signaling the other stations; requires but one call-receiving instrument at the central station, and but one spring-jack or other switching device or annunciator for each double wire circuit.

LEGAL NOTES.

THE GREAT WESTERN TELEGRAPH CO. LITIGATION.—DECISION FAVORING THE OLD MILWAUKEE STOCKHOLDERS.

The Supreme Court of Wisconsin has rendered a decision of great interest and importance to a large number of Milwaukee business men and one which may save the subscribers to the stock of the old Great Western Telegraph Co. a large sum of money. The action was that of the corporation named against the heirs of George Burnham and came to the Supreme Court on an appeal from an order of the Circuit Court for Milwaukee county overruling the demurrer of the defendants. The company sought to collect an assessment of 33 per cent. on the capital stock of the corporation, 100 shares of which were held by Mr. Burnham and fell to his heirs. Twenty years ago a number of Milwaukee capitalists were induced to subscribe various amounts to the capital stock of the Great Western Telegraph Co. The projectors of the enterprise were Chicago men. It was promised that 2,000 miles of wire should be strung. Lines were erected between Milwaukee and Chicago, with branches to neighboring towns. Notwithstanding this auspicious beginning, the enterprise collapsed within a very brief period from its inception. The affair had passed out of the minds of the stockholders. Their suprise was, therefore, the greater when they were served with notices by a Chicago attorney that suit had been commenced in the Supreme Court of Milwaukee county to collect an assessment upon the capital stock of the Great Western Telegraph Co. It was found that the debts and other obligations of the company aggregated something like $500,000, to pay which the courts of Illinois have authorized a levy of 35 per cent. upon the stockholders. It was set forth in the complaint, copies of which have been served upon the Milwaukee stockholders, that the subscriptions still constitute the means and fund for the prosecution of the corporation's business and the payment of its debts, that for a valuable consideration each of the defendants undertook and promised to pay for each share subscribed for by him the sum of $25, that the subscribers number 2,000 persons, living in twelve different States and territories, and that the subscribers neglect or refuse to pay the balance due from them to the capital stock of the company. The Milwaukee subscribers to the stock, when notified that suits were commenced, combined to fight the cases, and demurrer was made in the Burnham case. The Supreme Court now reverses the ruling of the Circuit Court of Milwaukee county, where the case is pending, on the appeal from the order overruling the demurrer of the defendants.

EDISON GENERAL ELECTRIC CO. vs. EDISON ILLUMINATING CO., OF CUMBERLAND, MD.—SUIT FOR DELIVERY OF STOCK DISMISSED.

Judge Bond, of Baltimore, signed an order dismissing the bill in the above suit. The case was in the United States Circuit Court, brought before it in November, 1889, and was argued before Judge Bond by Mr. Lewis, of New York, and Edgar H. Gans, of Baltimore, for the plaintiff, and E. J. D. Cross, of Baltimore, and A. Hunter Boyd, of Cumberland, for the defendant.

The plaintiff, says the Cumberland *News* of Dec. 20, is the parent company of the Edison system, and claimed in this suit that it was entitled to $5,340 of the stock of defendant under a contract made between the two companies when the contract was formed. Defendant claimed that the plaintiff was not entitled to the stock. The claim of the plaintiff was based upon a provision in the contract which provided that in case the Cumberland company gave any liens the plaintiff was to receive thirty per cent. of the amount in stock of the Cumberland company, this 30 per cent. being part payment for the use of the plaintiff's patent. When the Cumberland company had completed its plant as originally contemplated, it found that it was necessary to make further improvements and additions in the way of purchasing new engines, boilers, dynamos, etc., and the plaintiff claimed that it was entitled to 30 per cent. of the cost of these improvements. The Cumberland company had paid the royalty on the original plant and objected the payments on improvements and the dismissal of the plaintiff's bill will terminate this suit in the defendant's favor, and will relieve it of a claim that had a tendency to interfere with the Cumberland company making such improvements as it might otherwise have made in the past.

THE ADAMS CO. TO SUE.—A CLAIM OF PRIORITY IN ELECTRIC RAILWAY MOTOR PATENTS.

A special dispatch from St. Louis, of Dec. 26, says:—"It is announced here that the Adams Electric Railway Co., of St. Louis will within the next two weeks enter suit against the Thomson-Houston, the Sprague, the Short, and other electric railway companies whose systems are now in successful operation for infringement of patents covering the fundamental principle of propelling cars with electricity as the motive power. The claim upon which these proceedings are to be based is the official record of the Patent Office Department in Washington, backed by legal opinions from the mercantile patent lawyers in the country to the effect that the Adams Co. holds the patent under which every successful electric railway system of the country is now being operated."

ELECTRIC ACCUMULATOR CO. vs. BRUSH ELECTRIC CO.—AS TO DISMISSAL OF A SUIT.

A decision by Judge Henry B. Brown, of Detroit, who has just been appointed an Associate Justice of the Supreme Court, was filed in the United States Circuit Court at Cleveland, O., on Dec. 27. The case was that of the Electrical Accumulator Co., of New York, against the Brush Electric Co., of Cleveland, and the decision is upon the request of the Accumulator Company to dismiss a suit against the Brush Co., and upon the demurrer made by the Brush people to amended and supplemental bills of the Accumulator Co. Camille A. Faure was granted a patent on his secondary battery Jan. 3, 1882, and a month or two afterward a patent was granted on almost exactly the same invention to the Brush Co. The Faure patent passed to the possession of the Electrical Accumulator Co., of New York, and this concern began a suit against the Brush Co. to procure an adjudication of the invalidity of the Brush patent.

A demurrer and answer were filed by the Brush Co. affirming the validity of its own patent and denying the validity of the Frenchman's patent. The Accumulator Co. proceeded to take prima facie proofs and the Brush Co. to take its answering proofs. Then the Accumulator Co. filed a supplemental bill setting forth that the first claim of the Faure patent had been adjudged to be valid in the Circuit Court of the Southern District of New York. The supplemental bill alleged that since the filing of the disclaimer, the Faure and the Brush patents had not been interfering within the meaning of the law, and asked the court to dismiss the case.

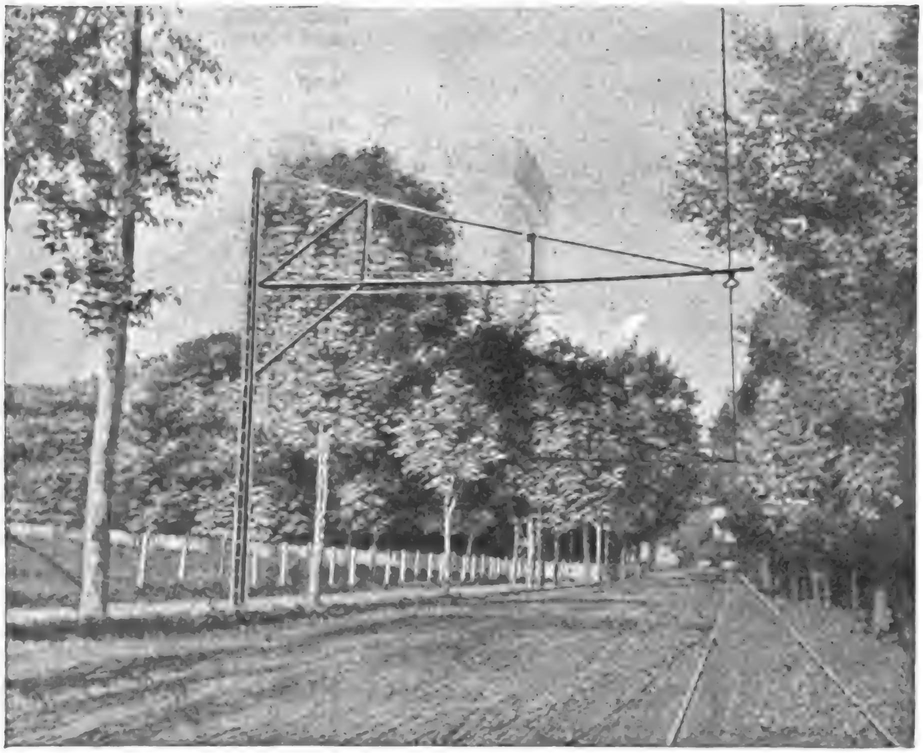
The Brush Co., however, objected to having it dismissed and denied that the two patents were not interfering. After citing many decisions Judge Brown said he had come to the conclusion that leave to dismiss a bill should not be granted where the action would be manifestly prejudicial to the defendant. The petition to dismiss the case was, therefore, denied.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

THE LARGEST ELECTRIC STREET RAILWAY POLE IN THE WORLD.

The cut on this page represents the largest electric street railway pole in the world. It was furnished by Messrs. Millikin Bros. to the Passaic, Clifton and Garfield street railway, at Passaic, N. J., only four of them being in use. The road runs its track on one side of the street and some of the property owners objected to placing poles on the curb line, so the owners of the road were compelled to place the poles on the opposite side of the street and throw an arm all the way across. This presented a difficult engineering feat and the parties, after giving the facts to Messrs. Milliken Bros., left them to design and execute the work. There were many serious difficulties to contend with in the support and bracing of an arm of such length on a single pole without the use of any guy wires from the pole to the ground. They used their usual form of pole and made the segments unusually heavy and extended the lacing from the bottom of the pole to the top.



THE LARGEST STREET RAILWAY POLE IN THE WORLD, PASSAIC, N. J.

The general dimensions of the pole are as follows: Length of pole, 35′ 0″; length of arm, 32′ 8½″; height of arm above the ground, 20′ 1½″; distance of pole in the ground, 7′ 0″; the pole is designed to carry 500 lbs. on the end of the arm and its total weight is 2,000 lbs.

The arm is built of angles and plates with proper struts and rods, most of which had adjustment. The arm was also braced in a horizontal plane on the lower chord, and the end of the arm has a loop and the same at a point near which it connects to the pole. This is intended for a No. 6 wire to be stretched from one pole to the end of the next arm to hold the arm against vibration, but we understand that for some reason this was omitted and not used. An ornamental acorn top was also arranged for, but when the photograph was taken it had not been put on. A sliding bracket to adjust the centre of the trolley line over the centre of the track is also provided.

The owners in writing to these parties in relation to other matters stated that these poles, although subjected to an unusually heavy strain, stood perfectly erect and were entirely satisfactory. We understand that Messrs. Milliken Bros. are even prepared to furnish larger poles than these if street railway work demands it.

MR. G. W. MANSFIELD, the expert of the Thomson-Houston railway department, delivered a most interesting lecture recently before the Business Men's Association of Pawtucket, on the subject of electricity, illustrating his remarks with frequent experiments.

LARGER QUARTERS FOR "A. B. C."

Whatever dullness is rumored to be prevalent in mercantile circles seems to have overlooked the supply trade, or at least a part of it. This is shown by the fact that the business of Alexander, Barney & Chapin, who opened their supply store in the Telephone Building, No. 20 Cortlandt street, only two and a half months ago, has increased to such an extent that they have been obliged to take in another whole floor, equally as large as their original capacious warerooms. As this firm has devoted itself particularly to the electric light and power trade, and in fact has covered the country from the east to the west and north to south, they handle specialties in immense quantities, and although the goods keep circulating—as one lot goes out another coming in—they have almost since their opening day found themselves overcrowded. They have accordingly called on their landlord for extra accommodations, and although space is scarce in Cortlandt street and room is valuable, have finally gotten the large basement under their store, which has hitherto been used by the Telephone Company.

This basement it is thought will be sufficient for six months, anyway, and it will be used as a storehouse, packing and shipping department. It and the floor above will be connected with an electric elevator, which will have the double advantage of being practically useful in the daily routine of business, and also of demonstrating to their numerous customers the working of this kind of apparatus.

INGENIOUS CATERING FOR PRIVATE TRADE.

Mr. J. M. Lennon, 22 Loan and Trust building, Minneapolis, who is now able to announce himself as agent for 31 electric companies, has issued the following ingenious circular to ladies in his locality, who are likely to need advice as to electrical decorations, etc: "Yourself and family are invited to call upon me when in need of an electrical expert's advice or assistance in installing and fitting any of the multitude of electrical conveniences, decorations, etc. And I should like very much to call your attention to the beautiful and æsthetic use to which the miniature Edison lamps may be put, either in the drawing-room, library, dining or other rooms. I have had a great amount of experience in this line and I am certain that the designing and fitting of at least one room in your home will both please and attract you. I can guarantee to leave your home in as perfect a condition as when entered, no matter how fine or frail the rest of the furnishings may be. Much use is being made of these small lamps by the elite in the East, in England and France. I also fit and design any of the finer grades of electrical apparatus, but cheap and gaudy fittings I will not do, as I do not care to do work for any but the elite of the Northwest."

QUEEN & CO.'S VANE AMMETERS.

Queen & Co., of Philadelphia, have recently taken an order for a "magnetic vane" ammeter, capacity 1,350 amperes. The instrument will have a dial some 12 inches in diameter, encased in a heavy japanned iron circular box. This is the largest ammeter that the firm has undertaken, and will, no doubt, be a handsome addition to the switchboard of the Central Passenger R. R. Co., at Louisville, Ky. Queen & Co. are also making "magnetic vane" ammeters with capacities of 300, 400 and 500 amperes for such companies as the Brush and Edison. These instruments have dials about 8" across and are mounted in iron or brass cases as ordered. They are used by the above companies on their finest switchboards where it is desired to have meters in harmony with the other work.

On the magnificent switchboard of the steamer "Plymouth" may be seen two of Queen's "magnetic vane" ammeters, capacity 400 amperes each. These instruments have been advertised but little as yet, but the demand is large and increasing, as the makers of dynamos are beginning to realize that in order to show up their apparatus in the most advantageous manner it is necessary to send out with each installation, first-class ammeters and voltmeters.

Queen & Co. also report a brisk demand for Ayrton & Perry ammeters and voltmeters, which are largely used as portable instruments.

THE BAIN BREAK INSULATOR.

The insulator illustrated below is designed to take the place of the ordinary devices that have been used as break insulators. The new insulator is made of one piece of porcelain, carefully glazed, and is so simple as to require scarcely a word of explanation; while its great strength and perfect adaptability are sure to commend themselves to all practical construction men. This insulator will be found especially useful, also, for suspending arc lamps from iron cranes, insulating guy wires, and particularly, for insulating span wires in electric railroad work.

THE BAIN BREAK JOINT INSULATOR.

The Central Electric Company, of Chicago, control the patent and are placing the device upon the market.

"NEW PROCESS RAW HIDE" STREET CAR PINIONS.

The question of gears for electric cars is a most important one, and is beginning to receive from the street railway companies the attention it deserves. There is still much to be learned. Thus, for example, discussing the topic of raw hide gears, the New Process Raw Hide Co., of Syracuse, say: "To the inexperienced buyer the term "raw hide" seems to cover all that is tough, noiseless and desirable for gears to be run at a high rate of speed. This is an error. By our patented process of treating the hides we are able to remove all that is useless, only retaining the actual fibre to the full extent of its strength. No other process known can do this, and while to the casual observer one raw hide gear seems as good as another, yet by actual test we are as far ahead of the ordinary makes as steel is ahead of iron. Both may have pretty much the same general appearance, but a comparison is not to be thought of. Beyond our patented process of preparing the hides we have the only patent in existence for a gear with face entirely of raw hide, and these in conjunction put us into the field with an armor well calculated to protect and save us from the shafts of our competitors, and give us the preference so well deserved."

The company are recently in receipt of the following communication from the Wichita, Kansas, Electric Railway Co:

"Replying to your favor of Dec. 6th, will state we have used your raw hide gears off and on since last May, together with various other kinds of pinions. We believe that your raw hide pinions are the best in the market at the present time.

"The first one we put on in May 1890; this pinion was in service seven months, and was not then entirely worn out. Yours very truly. Signed. Thos. G. Fitch, General Manager."

A PORTABLE PHOTOMETER FOR CENTRAL STATIONS.

Heretofore photometer work has been but little practiced by managers of central station plants, one reason being the cost of the apparatus, and another its apparent more intimate connection with the laboratory than with the manufactory and salesroom of electrical illumination. The first objection (if it may so be called) has been overcome, however, and as regards the second, the sentiment has now veered around and the demand for photometrical measurements in practical work is becoming well established. Alexander, Barney & Chapin are now introducing a portable photometer, which is noticeable chiefly for its inexpensiveness and adaptability for general work. The lantern is so made that when not in use it can be thrust entirely into the photometer box. When in use it is placed upon an ordinary photographic tripod; it can be reversed so as to allow for difference of vision of two eyes. When not in use, slides cover the ends of photometer and sight box, while a handle on one side allows of convenience in carrying. The range of the measurements is from about 7 to 2,000 candle power.

The method employed in measuring is as follows:—Place the lamp to be measured in front of the opening in the photometer box, away from the standard candle. Move the lamp to and fro until the diaphragm is illuminated equally on both sides, then measure the respective distances of the standard candle and the lamp from this point. Employ the formula $S : L :: A^2 : B^2$; in which S is the standard, L the lamp to be tested, A the distance of S from the diaphragm, and B the distance of L from the same point. For convenience the standard candle is usually placed 1 foot from the grease spot, in which case A may be ignored in the formula. Thus, if a standard of 1 candle be used, and the lamp is four feet from the spot, the proportion will be $1 : L :: 1 : 16$. The lamp therefore gives 16 c. p. In measuring lamps of high candle power it is sometimes not convenient to place them at the necessary distance from the photometer, in which case it is best to use two standard candles, which reduces the distance to one-half. For testing arc lamps suspended in the street, it is necessary to reflect the light by means of a mirror into the photometer box.

This apparatus is sold by Alexander, Barney & Chapin, of the Telephone Building, 20 Cortlandt street, this city, who have already put out quite a number. We illustrated it May 14, 1890.

THE RAE ELECTRIC RAILWAY SYSTEM.

The Detroit Electrical Works are now running double time to meet the demand for their Rae electric railway system, orders for which pour in from all sides. An evidence of the approval enjoyed by the system is seen in the second order from the Galveston road, for ten cars, making 30 Rae cars in all, or half the full complement of the road. The cars already in use are running nicely and the new ones are wanted as soon as possible.

THE GREAT WESTERN ELECTRIC SUPPLY CO., of 190–193 Fifth avenue, Chicago, ask all who have received quotations from them to cancel same, and to write for new ones on any supplies they may need. In the near future they will issue a new catalogue and discount sheet, which will be forwarded to all their friends and patrons, so as to give them promptly the benefit of the new prices.

THE HIMMER AND ANDERSON DRY BATTERY CIGAR LIGHTER.

ONE of the recent uses of the popular dry battery is that shown in the accompanying cut of a cigar lighter just brought out and placed on the market by the Himmer and Anderson Dry Battery Co., of this city. It should certainly displace the match box and its elusive contents. It has a couple of dry batteries inside the case, with a spark coil in the rear and the sparking terminals in front, as indicated, above a small tray and immediately under the winged head. The case is of ornamental wood, surmounted by a stag or other desirable piece of bric-a-brac or stationary. As will be seen this is a portable, handy, lighter, as convenient as anything of the kind could well be.

"MAKE IT PAY."

Edwin L. Burdick & Co., of Buffalo, N. Y., under the above title, have issued a very pithy little brochure devoted to a discussion of advertising and of the merits of the *Roller Mill* as a medium in its special field. The remarks on advertising are most excellent. Its motoes are of the kind that deserve to be posted on the memory, and lived up to by every advertiser who would get the worth of his money. The *Roller Mill* is a paper of high reputation and large circulation, and is not only a recognized authority but is a model of typographical beauty and finish, of which Burdick & Co., its energetic publishers, may well feel proud.

COLUMBIA INCANDESCENT LAMP CO.

The above company of 1912–1914 Olive street, St. Louis, Mo. has just issued a tasteful catalogue and price list of its incandescent lamps. The cover is adorned by a graceful figure of Columbia holding up a lamp deriving current from a dynamo at her feet, and the inside pages are freely illustrated with cuts of the various sizes and styles of lamp, for Sawyer-Man, Edison, United States, and Thomson-Houston sockets. Lamps are also made for Swan, Hawkeye, Queen City, Fort Wayne, Schaefer, and other sockets, and old lamp bases will be refilled, with an allowance for the base. The company is also manufacturing a special lamp for use in electric cars, the filament being so mounted as to prevent mechanical injury from vibration. The company's factory is fully equipped with the latest appliances and tools, and superiority for the product is claimed on the ground of its candle power, long life and high efficiency. J. H. Rhotehamel is the president and manager.

MORE CHANGES ON "THE ELECTRICAL WORLD."

Our contemporary, *The Electrical World*, published in this city, announces that it has made further changes in its *personnel*, having secured for its New York offices the services of Messrs. F. De Land, W. Hazen and J. F. Dillont. They take the place of Mr. Clarence E. Stump, who has lately withdrawn from that paper, of which during so many long years he had been the faithful and efficient business manager, a capacity he will now fill for the progressive *Street Railway Journal*. Of the newcomers, Mr. F. De Land is the only one known in electrical journalism, and his many friends, among whom we gladly count ourselves, will desire for him personal success under the circumstances that have necessitated his removal to the East. To him and his new colleagues in the conduct and management of the paper, we beg to extend our wishes for their happiness—and long tenure of office.

NEW WESTINGHOUSE CONTRACTS.

Since the first of December, the Westinghouse Electric and Manufacturing Company has received contracts for alternating current electric lighting apparatus for a capacity of 5,650 incandescent and 120 arc lights. Olean, N. Y., has contracted for an increase of its plant and when the new apparatus has been installed, the plant will have 1,400 incandescent lamps' capacity. The alternating current electric lighting plant of the Missouri Electric Light and Power Co., in St. Louis, Mo., has grown so rapidly that it has now become one of the largest central station plants of alternating current electric lighting in the United States. The company was organized in the early part of 1887, with apparatus of a generating capacity of 12,000 lights. This was the first contract for Westinghouse alternating current apparatus which had come from St. Louis. The other systems of incandescent lighting of the larger companies in America were already in operation in that city, but nevertheless, the Missouri company found a very ready demand for its lights, and the success of the plant was assured from the very start. This fact very soon manifested itself when the management found that the supply at the central station was not sufficient to satisfy the demand any longer and an increase had to be made in the generating capacity. A 3,000 light Westinghouse alternating current dynamo was added and for a time the immediate wants of the company's patrons for lighting were complied with. But it was only temporary and then the company added two more 3,000 light Westinghouse alternating current dynamos to the capacity of the station.

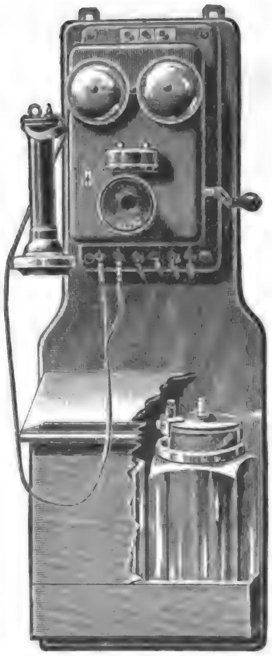
The company now had a generating power by which it was enabled to furnish 21,000 sixteen c. p. incandescent lamps, which made it the largest electric lighting plant in St. Louis, but the new system of lighting had by this time gained such a popularity among the people of the city that the supply was again taxed to its utmost capacity until a few days ago, the Westinghouse company received another contract for the installation of one of its 3,000 light apparatus. This will give the Missouri Electric Light and Power Co. alternating current apparatus with a generating capacity of 24,000 incandescent lamps, which makes it the largest alternating current central station plant in America, west of the Allegheny mountains.

The Pennsylvania Railroad Company is rapidly increasing the number of electric light plants along its lines, where a good light is of the greatest consequence and advantage to the railroad. Some time ago, the Westinghouse Electric and Manufacturing Company installed a plant of its alternating current arc light apparatus at the Altoona shops. The operation of that system has given such satisfaction that the railroad management lately decided to have a similar plant put up at Wall station, which is one of the most important points on the entire Pennsylvania Railroad system. The plant will have a capacity of 120 arc lamps.

The electric light plant at Wilmerding, Pa., the new town near Pittsburgh, where the Westinghouse Air Brake Works are located, is now being increased from a capacity of 1,500 to 2,000 lights.

THE BERLINER "UNIVERSAL" TELEPHONE TRANSMITTER.

The "Universal" transmitter was designed by Mr. E. Berliner with a view of supplying an instrument which would be efficient both as a microphone for short lines and with only one cell of Leclanché battery as well as on the longest commercial lines where



BERLINER "UNIVERSAL" TRANSMITTER.

several Fuller, or Bunsen, or accumulator cells become necessary.

It is well known that the Blake transmitter works excellently on shorter lines and when these are in first-class condition. But when the lines are leaky or troubled by induction from neighboring lines the "Blake" loses its power to give satisfaction, particularly as the construction does not admit of the use of larger battery power owing to the liability of the contact to "stick" or burn.

Many attempts have of late years been made to supplant the "Blake" by a multiple contact transmitter or one in which carbon granules enclosed in a chamber are used, but thus far, with the

exception of the "Universal," hardly one has succeeded entirely in supplying at the same time sharpness of articulation, facility of speaking at leisure away from the mouthpiece, economy of battery, and foremost, the avoidance of clogging or "packing" of the carbon granules.

It is true that for some time a "long distance" instrument has been in use in the United States, but it is necessary to speak close to it and with one cell of Leelanché it is not superior to the "Blake." It also requires frequent shaking up, although this should not form a serious cause for complaint.

In the "Universal" all the requirements of a first-class transmitter are combined and all sources of annoyance have been eliminated. With one cell of Leclanché it is superior to the "Blake" and will carry the voice over a defective line where the "Blake" utterly fails. With three large Fuller or Bunsen cells it retains its purity of intonation and produces a volume of sound which on lines several miles long would still fill a lecture hall when a funnel-resonator is applied.

It may be spoken to either three to six inches from the mouthpiece in an ordinary tone of voice, or, if necessary, close to it with the loudest voice.

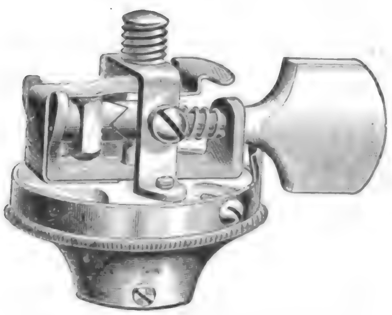
Its internal parts, diaphragm chamber and granules are all carbon, with a thin covering of mica to prevent the breaking of the diaphragms The granules, when viewed under a lens, show rounded corners and the resistence of the mass is lower than that of other masses of granules used for this purpose. A striking novelty is the use of a soft rubber mouth-piece which helps making the instrument sensitive without adding a bad quality to the articulation.

Special care is bestowed on the induction coil so that even governments who from motives of patriotism favored transmitters made by their home talent, ordered coils made in Hanover to use in connection with the "Universal."

It is almost to be expected that the many years of experience which Mr. Berliner has brought to bear on his first invention should enable him to produce an instrument which has now and then been approached in certain points, but which taken as a whole has no match or rival among the many forms of transmitters which have been designed after Mr. Berliner first incorporated the principle of loose contacts into the science of telephony. The Tropical American Telephone Co. has the exclusive export agency for the "Universal" long distance telephone sets.

THE "E. E. & S." KEY SOCKET.

The E. E. & S. key socket, manufactured by the Electric Engineering & Supply Co., of Syracuse, N. Y. is adapted by slight modifications for use in connection with the Thomson-Houston, Edison and Westinghouse systems. One of the chief features



THE "E. E. & S." KEY SOCKET.

wherein it differs from other key sockets is that the insulating parts consist entirely of air spaces, and a peculiar quality of porcelain so tough that the parts may be riveted to it without breaking the porcelain.

The end to which the lamp is attached has an air space insulation doing away with fibre or other insulation used in connection with most other sockets. The base of the "E. E. & S." key socket is of porcelain, which is a tough non-absorbent porcelain practically indestructible.

The make and break arrangements are governed by a peculiar form of clutch operating a cam which throws the silicon-bronze contact spring, producing a slight wiping contact. The break is very sudden, owing to the peculiar operation of the clutch mechanism and is expedited by the operation of the contact spring itself as well as a small spiral spring, which produces a very quick break. The motion, however, is a positive make, with the sudden break, which owing to the lost motion on the clutch mechanism is as rapid as can be produced by parts operated by the two springs.

Another peculiar feature of this socket is the finely finished china porcelain key which is free from the softening experienced in keys when exposed to somewhat high temperature.

The good features of this key socket have already created such a demand for the article that the manufacturers been obliged to operate their factory nights and have already ordered more than double the present equipment of machine tools to put into their new factory. This they hope will enable them to keep up with their orders for this and their other electric lighting and railway specialties.

NEW ENGLAND TRADE NOTES.

MR. L. H. ROGERS, New England agent for the Brush Electric Co., has sold a 600 light Brush alternator to the Manchester Gas & Electric Light Co., Manchester, N. H. The station has been laid out to accommodate two more alternating dynamos of 1,000 light each. A 500 horse-power compound condensing engine is being installed.

THE STANDARD ELECTRIC CO., OF VERMONT, have sold a 500 light plant to the Olcutt Falls Co., Olcutt Falls, Vt.

THE PORTER MANUFACTURING CO., of Syracuse, N. Y., manufacturers of the well known Porter engines and boilers specially adapted for electric lighting purposes, have opened a branch office at 218 Congress street, Boston, with Mr. W. S. White as manager. Mr. White has been for eight years master mechanic for the Cocheco Print Works, Dover, N. H., is thoroughly conversant with all classes of engine work, and is well known in New England. A full sample stock of engines and boilers will be kept, and orders for the smaller engines will be promptly attended to from the Boston office.

MR. E. M. CARHART, of Providence, R. I., well known in New England as having been for years general manager of the Rhode Island Electric Protective Company, of Providence, having severed his connection with the above company, has sent out notices to his numerous friends and former patrons that he has opened an office at the old address, 18 Customhouse street, Providence, under the name of E. M. Carhart & Co., where they will carry a stock of new and most improved supplies for electric lighting. Among their specialties will be the new Thomas mast arm and the Thomas tree iron. All kinds of electric wiring for light, bells, annunciators, burglar alarms, etc., will be done, and it is contemplated establishing a new district patrol system for fire and burglar alarm in the city of Providence.

WESTERN TRADE NOTES.

MR. H. R. NOYES has resigned from the managership of the Chicago Electric Club and will return East to his home in Boston, where he will assist his father Judge Noyes in the management of his many large interests there. During Mr. Noyes' occupancy of the post of manager he has become a universal favorite and has made for himself a host of warm friends amongst the electrical fraternity.

MR. W. PEYTON SULLIVAN will succeed Mr. Noyes as manager of the Chicago Electric Club. He has been identified for many years with the paper manufacturing trade in Europe and this country, and was, till his coming to Chicago about a year ago, a resident of Ypsilanti, Mich. He has since been connected with the Chicago office of the Pond Engineering Company, as assistant to Mr. Albert Blanchard, the widely known manager of that company. Mr. Sullivan is eminently fitted for the position and will no doubt ably look after the club's interests and the management are to be congratulated on their selection as is also Mr. Sullivan upon his connection with the club which is in a most flourishing and prosperous condition.

THE KNAPP ELECTRICAL WORKS report business as very brisk and the outlook for the coming year as most flattering. They are constantly receiving large orders for the famous Grimshaw white core and other wires and cables, Perkins' lamps and the other specialties which they handle.

MR. GEORGE CUTTER has gone East on a three weeks' trip and will return undoubtedly with many new specialties for electrical work and also plenty of orders for the same from his many friends and patrons all over the country. He is devoting his time to handling specialties of merit and his quarters in the Rookery are filled with all kinds of new and useful devices many of which are the outcome of his own fertile inventive genius.

THE ELECTRIC MERCHANDISE CO., 11 East Adams St., Chicago, have just issued to their numerous patrons a handsome little illustrated circular calling attention to a few of their new specialties. Mr. Stevens' "Positive Gravity" switch, a new fuse-box, the Mason lightning arrester and a novel and advantageous platform gate for street cars are all clearly shown and their many merits brought to notice.

THE HAZLETON TRIPOD BOILER CO., No. 170 Twenty-second street, Chicago, report business good and prospects for the coming year very encouraging. Their recent sales include shipments to Mexico, Montana, Washington and Wisconsin, and they are now erecting two 500 h. p. boilers in Youngstown, O., and the second 500 h. p. for the Citizens' Street Railway Co., of Indianapolis; also two 400 h. p. and one 350 h. p. for the electric road in Rock Island.
